Thanks to all for your replies
With regard to Tim's idea of the dual comparators, I presume these would in "series". For the integration idea to work, the comparators would obviously have to have their gain set carefully, otherwise random noise would integrate to 1/2 time and be interpreted as signal. The circuit I was thinking of would set the DC comparison point at halfway (say 2.5V for a 5V logic level) with the DC level of the signal also at 2.5V. I presume in your system the uP controls the comparison voltage and sets it with a DAC and the signal DC level is 0V. Is this correct?
In my idea I was going to use the timing of signal transitions in a hard limited signal. If there were several transitions with the same timing, I would presume a "tone" was present and signal was being received. Randomly timed transitions would indicate noise.The uP could follow the tone as an adaptive filter to track carrier freq. Once carrier is received the uP then captures dot, dash and space timing with the histogram as you describe. If a moving average filter of these is kept, then the uP could track sender speed variations.
Anyone have ideas as to the theoretical performance of such an idea or any potential problems?

Thanks again
Richard

Leader is still active in supplying them. I'm assuming you need the service manual. I called them and spoke to a lady in their parts department who emailed me the owners' manual for free and quoted me US$80 for a printed copy of the service manual. I couldn't find a freebee service manual for my 8100 'scope though. If you find a source, thanks for letting me know.

see Leader at http://www.leaderusa.com/

Check the hardware store for electronic watering timers. There are some
that work from AA batteries. Hack it open, replace the motor with a
relay. You will probably need a latching relay arrangement or be
otherwise creative as the timer runs the motor for a few seconds open
and closed.

http://www.usbid.com/search/results1.cfm
I assume you are looking for Zero Bias Schottky diodes. These are similar to the diodes that are used in the Boonton RF Probes. Turn-on level is around -54dBm. If you don't need the Zero Bias types, I've got a reel of SOT-23 types that are good toe 10GHz. I would be willing to sell a few of these.

> In my idea I was going to use the timing of signal transitions in a hard
> limited signal.

You really don't want to muck with limiting. Probably the biggest challenge is differentiating the signal from the noise. If you limit the signal, what you have done is brought the signal level closer to the noise level, making your detection problem more difficult. Typically, the signal is higher than the noise almost all the time, so what you want to do is have some sort of threshold below which you will assume is noise. You are still going to have to deal with the occasional pop.

> If there were several transitions with the same timing, I
> would presume a "tone" was present and signal was being received. Randomly
> timed transitions would indicate noise.

This approach makes some sense, although I'm not so sure that a simple approach like a 567 or 2211 wouldn't accomplish the same thing with less effort. Keep in mind that the frequency of those transitions is also going to be limited to a fairly narrow range if you are receiving CW. But separating the CW from the noise isn't as simple as it sounds.

> moving average filter of these is kept, then the uP could track sender
speed
> variations.
> Anyone have ideas as to the theoretical performance of such an idea or any
> potential problems?

Again, you have the same challenge OK3OIL's code has. You need to be fairly responsive to speed changes or it can take a long time to lock on to another station. But, you don't want to allow strings of the same element to confuse you. Strings of a dozen or more dits are fairly common, both as an error indication and in words like less. On the other hand, numbers like the year 2000 can result in a long string of dahs. The big challenge is keeping the response to changes while not being mislead.

Greetings,

I figures that this would be the BEST group to ask these questions. I am getting back into building after quite a while. I am putting in a section in the attic shack for testing and fabrication and have am starting to equip things. I already have some relatively good test gear, Tektronics 475A, DM44, sig generator, etc. but want to set up for fabrication. I have been wondering what most of you find as indispensible on your benches. I really want a PCB vise/holder that would aid in the fabrication process.

If any of you do your own design/fab of PCBs I would also be very interested in what you find are the best tools/techniques. If you are using software to go from circuits to black PCB mask I am VERY interested in this (freeware/shareware is best). I have been reading some of the sites but I am most interested in what you as experienced homebrewers like the MOST.

I have done some kit building and fab long ago but I have been out of it for quite some time. I have ordered an elecraft K1 to get my soldering back into shape ;-)

Many Thanks and 73,
Vaughn

Just thought I would mention to all newsgroup readers the incredible deal available from Zilog. They have their Zilog Encore Z8 development kit, which includes a development board, eZ8 processor, C compiler, assembler, simulator, IDE, cabling, documentation and more for a mere $40 US (available from Mouser and others).

I have been using this development kit for a few months. It is a fantastic way to learn about microprocessors, microcontrollers, C and assembler programming, for a great price. A C compiler alone will cost you more than $40 for most controllers. I have no beneficial interest in Zilog, but their product is terrific.

contact cleaner is usually sold as a can of aerosol-spray.

I seek it in swab/wipe form, preferably in unit-pack. Lots of alcohol-water pads out there, I don't want to put water on my equipment. Anyway, it takes the real solvents (eg, hexane) to get the bad crap off. I'd settle for acetone swabs, I suppose.

Who sells the stuff? URLs, snail-mail contact info?

The piece of test equipment that I've found most critical is my brain. Whenever I forget to use it bad things happen. If you're doing radio buy or build a good dip meter. They're hard to find new, but you can find them at hamfests and there's still nothing better for checking out resonant circuits.

When I'm building circuits for through-hole components I just use dead-bug construction. There are numerous articles in QST on the technique, and the newer ARRL handbooks detail some of the methods. I prefer the ground-plane style where you never cut up your circuit board at all.

If I did need a circuit board these days I would be _very_ tempted to use one of the gazillion quick-turn PCB houses out there. There are a number of them that are oriented toward the hobbyist, and they do surface-mount quality boards (at least one, ExpressPCB, offers a kit for doing reflow in a toaster oven as well). Most have an "economy" rate where they charge around $80 to do a pair of 3"x5" boards, and their "regular" service isn't all that bad either. Unless you are very desperately poor I'd recommend that you check them out.

23. Kenwood TM-231A help needed

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-01 22:48:05 UTC
From: Don Smith <desmith@innercite.com>
Message-ID: <vv95cpgrf1cid5@corp.supernews.com>

Cross-posted to: rec.radio.swap,rec.radio.amateur.misc,rec.radio.amateur.homebrew,rec.radio.amateur.equipment

I have a Kenwood TM-231A that I am trying to modify the frequency range. When I got it the radio was able to receive from low 2-meter frequencies to 160mhz plus but the transmit was only to about 148mhz. When I tried the installation of the D209 diode per the modifications instructions and service manual I lost the upper receive frequencies and only had the 2 meter frequencies. Is there something I am missing? Is there some other component that needs to be added or removed? Does the CPU have to be reset in any way.

Also I do not have the TSU-6 tone board installed. Will the radio still produce encode tones and if so, how do I change tones? Please respond by email. Thanks, 73's and Happy New Year to all. Don smith KB6GQA

Hi Alan,

http://www.caig.com

Caig labs makes Deoxit brand contact cleaner in spray, wipe and swabs.
Little expensive but you use microscopic drops at a time,
also works great on those scratchy pots !

Vaughn -

I have been very happy with the PanaVise products for vises and PC board
holders.

I have use the Weller "TCP" series and "EC" series soldering stations for
almost all of my kits since 1975.

Some Radio Shack digital AC timers actually run from batteries - run
even without AC present. (hit the "manual ON" switch & listen for the
relay to click with the unit not plugged in to AC)

Yeah, I have the z8!Encore dev kit (ï¿½23), not bad at all.

Complete dev kit, including in-circuit debugger, can't complain at that,
although their compiler has a few bugs (especially when code optimization is
enabled).

The 6.30 IDE (and I assume the 6.40, didn't check) requires that Internet Exploder be installed, I don't recall if it's 5 or 5.5, but a fairly recent version. As best I can tell, all it does with IE is splash up some readme's about a bunch of USB drivers, but the install checks for IE and won't install without it. Wouldn't surprise me if it also checked for SE or later, but that I didn't verify.

Original article starts here:

A great feature of a personal-computing hobby is that it can be used
to work with other hobbies. A case In point is

this little program to decode and print out Morse code. I original-ly
wrote this in machine lan-guage for my KIM

system, where it took up less than one page, and finally decided to
try it in BASIC.
Even though the program looks simple, it has some unusual surprises,
such as self-adaptive adjustment for changes

in code speed. In addi-tion, the influence of changes in dash or dot
length is weighted so that they must occur

five or six times in succession be-fore the computer decides that
there has been a bona fide speed change. As a

result, an occasional "bad" character will not mess up your copy; the
printout is extremely stable and the copy is

relatively foolproof.

The program also detects the end of the word and prints out a space, if required.
The program's memory needs are minorï¿½just a little over 1K of RAM is required. The program is written in Microsoft

BASIC on the KIM computer, but should operate with any relatively fast BASIC. From a hardware standpoint, if your

CRT or printer will go to 300 baud, this program will provide excellent copy of Morse code, up to 15 or 20 words

per minute. If your terminal operates up to 1200 baud, it will follow the Morse transmissions to well over 30 words

per minute.

Loading the Program

Input the program exactly as written, even though some of the instructions may seem re-dundant. It is written this

way to save operating timeï¿½a very important consideration when you are dealing with fast-acting dots and dashes.
Lines 10,20, 60, 110 and 150 instruct a PEEK to location 5888 (decimal). In the KIM com-puter, this is a peripheral

input address at 1700 (hex). This loca-tion reads a total of eight input ports as an eight-bit word.
The AND 1 on lines 10,20,60, 110 and 150 assures that the computer is only reading the port to which the incoming

Morse is connected obviously, this must be changed to fit your particular system.
In addition, the program assumes that when a dot or a dash occurs, a logic 0 appears on the input port. This is in

agreement with a "key down" shorting the input port to ground, and also in agreement with the hardware interface

cir-cuit described later. If your hookup provides a logic 1 during a dot and a dash, then lines 11, 30, 70,120 and

160 must be changed so that all IF A = 1 statements should read IF A = 0, and vice versa.

Program Description

Fig. 1 is a simplified flow diagram of the program. The initialization routine (lines 1 through 6) sets the lookup

table that will permit the printout of the proper character. The pro-gram then waits for a key down to occur (lines

10 and 11). The first part of the operating pro-gram (lines 20 through 80) mea-sures the length of time that the

key is down and compares this with the stored value for the length of a dash.
If the key is raised in less than one-half of the stored dash time, the computer writes a dot into the dot register

(line 30) and goes to the second part of the operating program.
If the key remains down longer than one-half of the dash time, a dash is stored in the dash register (line 50), and

the value of the dash time is up-dated with a one-to-four weight-ing (line 80). This is accom-plished by

multiplying the old value of the dash time by four, adding the new value, and then dividing by five. As a result,

the stored value of the dash time cannot change drastically from character to character, and the copy is not

susceptible to er-rors from erratic sending habits. The second part of the pro-gram (lines 100 through 190)

measures the length of time the key is up. if it's up less than one-half of the dash length, the program assumes

that the character is not complete and no printout is provided (see lines 100 through 130). If the key is up

longer, the program jumps to line 300, the print-character subroutine. If the key is up longer than twice the dash

length, the program assumes that a word is complete and a "space" is printed (lines 170 and 180).
Lookup Table
The heart of the program is the algorithm that counts the dots and dashes and develops a number used to look up the

ac-tual character to be printed, in other words, each combination of dots and dashes in Morse code has a discrete

number that commands a given character to be printed. This algorithm has three conditions as listed in Table 1.
Steps 1 and 2 keep repeating until the character is complete. When the program detects a key-up period longer than

one-half of a dash length, it is assumed that the character is complete and step 3 is accomplished (lines 300 to

430). The manner in which the lookup number for the letter D is formed is shown in Example 1. Interlace Hardware
Fig. 2 shows a typical circuit for connecting your radio re-ceiver to the computer. The NPN transistor is an R/C

coupled audio amplifier con-nected to a type 567 phase-lock loop circuit. The free-running frequency of the

phase-lock loop is set by the values of the capacitor and resistor con-nected to pins 5 and 6 of the 567, and is

approximately 2000 Hz. The capacitors on pins 1 and 2 of the PLL adjust the bandwidth to about 100 Hz, and the LED

serves as a tuning in-dicatorï¿½that is, It will start blinking when the signal Is in the center of this narrow

band-pass. This circuit is compatible with the program, as written, In that the output signal goes to a logic 0

when a dot or a dash occurs. The circuit shown is not my original idea, but has appeared in numerous publications;

you may have your own favorite circuit that you would like to use. As long as you maintain the same output logic (a

0 for a dot or dash), there will be no problem.

Incidentally, the circuit has another unique application. Since it is only activated by audio signals over a fairly

nar-row band, it can also be used to key an audio oscillator set to any frequency desired. When Morse CW comes in

amidst a jumble of other signals, the phase-lock loop picks out the signal you want and keys the audio

oscillator... and that is all you hear. A full-scale outline of the circuit board is shown in Fig. 3.
Adjusting the Program One of the advantages of writing this program in BASIC is the ease with which the com

putatlon constants can be changed. For Instance, you may wish to experiment with different algorithms to detect

whether a key-down signal is a a dot or a dash... to take care of "swlng-fisters." This can be accomplished easily

by chang-ing the factor in line 40 from (.5*0) to (.2S*C or <.75*C). By the same token, the constants In lines 111

and 151 can be changed to provide more lee-way for the formation of char-acters and spaces.

1. If the input signal is a dash:
A. Double the values in the dot and dash registers.
B. Add 1 to the dash register (see line 50).
2. If the input signal is a dot:
A. Double the values in the dot and dash registers.
B. Add 1 to the dot register (see line 30).
3. if the character is complete:
A. Double the value in the dash register.
B. Add the dash and dot registers to obtain the lookup number.
C. Clear the dot and dash registers.

Table 1.

EXAMPLE: D = -..

initial conditions: Dot register = 0, Dash register = 0.

First period: Input a dash.
2 times dash register =2x0 = 0.
2 times dot register =2x0 = 0.
Add 1 to dash register =1+0 = 1.
Summary: dash register = 1, dot register = 0.

Second period: Input a dot.
2 times dash register =2x1 = 2.
2 times dot register =2x0 = 0.
Add 1 to dot register =1+0 = 1.
Summary: dash register = 2, dot register = 1.

Third period: Input a dot.
2 times dash register =2x2 = 4.
2 times dot register =2x1 = 2.
Add 1 to dot register =1+2 = 3.
Summary: dash register = 4, dot register = 3.

End of Characterï¿½-determine lookup number for D.
2 times dash register =2x4 = 8.
Add dot register and dash register =8 + 3 = 11.
Answer: D = 11.

Example 1.

BASIC Code:

```
1 REM MORSE CODE READER - WRITTEN BY R. KURTZ - W6PR0
2 RESTORE

Um, what sort? Are you looking for low-level input with low noise and low distortion? Or are you looking for power output stages? How much power? Are you looking for something that will run efficiently from a battery supply, or will it be line powered? Do you have power supply voltage preferences? Please tell us a bit more about what you want to accomplish.

A visit to web sites like http://www.analog.com/index_noflash.html, http://www.national.com/, and http://www.ti.com/ will get you to selection trees and data sheets for audio (and other) ICs. All three of those have interesting ap notes and articles about various aspects of audio design, too. You can also make very high quality audio stages with discrete parts, but if your time is worth much, those might not be so cheap as the modern IC solutions.

Cheers,
Tom

Since it was some interest for it, I've put some different approaches
on my page http://home.online.no/~la8ak/c11.htm
Also came across a similar detector used for SSB/AM in Drake R4245
receiver (for 50kHz IF)
Have tested MC1351P, MC1496CP, S042P, TBA120 for similar applications
and reference is shown on the page.

It is somewhat frustrating to see new AM receivers presented - even
using ring mixers and smd components - but they forget about the
detector, at least they could have used a simple quadrature detector

47. Re: what lead-free solder do you use, and where can I buy it?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-02 22:19:13 UTC
From: see_signature@airmail.net
Message-ID: <3ff5e6f7.19188215@library.airnews.net>
Source record: 29834

In my production engineering job I would routinely hold
my breath and stick my head in over the solder wave in the
wave solder machine. Large amounts of soldering fumes would
come up from that molten commercial-grade organic solder.
After pulling my head out, I'd exhale. One time I did this
maybe 20 times a day for a week in the pursuit of soldering
refinements.
Aggravated by poor sleep from a change in the work
routine, my health went down hill quickly. My ankles were
puffing up, possibly indicating the onset of liver disease.

I got the message. I stopped exposing myself to the
airborne lead and flux particles. It took several months
for the swelling of the ankles to go away.
Workers at the factory would set up muffin fans to suck
the hand-soldering fumes away from them. This is a good
idea. Otherwise, the fumes seek out the rising column of
air around one's body and are thus breathed in directly.
Also, most people lean over the work while soldering.
Doing soldering next to muffin fan and a cracked
down-wind window should readily resolve the problem for the
most cautious hobbyist solderer and family members.
Regarding someone's comment about putting solder in his
mouth: Remember the historians' speculations about the
contribution of lead wine vessels toward the fall of the
Roman empire. Also, I can taste regular spool solder. That
means I'm dissolving something from it.

I'd guess the Zilog kit, like the PICkit, uses a USB interface. No
support in Win98 1st edition as released (although I believe that one
can install an aftermarket USB support package).

Hi Henry, that was not the best idea in the world, but I have been soldering for over 40 years, and have never experienced any health symptoms like you describe. I solder a lot, both at work and at home as a ham. I'm 57 and never had health problems. I think you should look for other sources for your apparent health problems.
As has been stated, the fumes are from the flux, and I have inhaled a bunch of it:-). The lead portion can only hurt you if it is ingested, not sniffed. I am sorry you had health problems, but it may not be for the reason you think.

Yes there are such animals out on the commercial market. It's often used
for emergency radio systems in tunnels (like the Alp tunnels!) Where you
have the need to send on all frequencies if something goes awry!

Mostly on the AM band but I think the same method is used for the FM band
as well. Ans yes, they use only one transmitter!

The basic principle is to take all available channels, 25 or 50 kc
separation. take the output
from all those channels and superimpose them on one signal carrier. The
resulting 'waveform' will then contain al channels and you just modulate
it and feed it to a broadband amplifier. For the AM broadband transmitter,
this is done by sampling the resulting signal and store it on an eprom
and use that as the input to generate a multifrequency signal.

Remember the old G3RUH modulation for 9600 baud, where its many
frequencies put together to generate the composite signal, which can be
taken apart by a receiver again.

Cheers

Sorry if this sounds weird, but if you wanna listen to the real case, just
drive down in the europe alp tunnels!

51. Tuna Tin (II) output impedance

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-03 00:38:57 UTC
From: Gary Morton <gary@alma.demon.co.uk>
Message-ID: <BaoJb.5320$qA5.52892911@news-text.cableinet.net>
Source record: 29838

Over the Xmas break I constructed a simple 2 transistor QRP transmitter using the Tuna Tin II design.

Using a power meter and a 50 ohm dummy load it appears to show around 200mW, a little less than the article suggested. Then again I had substituted the final stage 2N2222 transistor for a beefier (size wise) BFY51. I'm not too sure what exact difference this will make.

In the article it says that the 200 ohm output impedance of the final stage is transformed down to around 50 ohm (using a 2:1 turns ratio untuned transformer wound on a toroid).

I have added a 7th order low pass filter to reduce the harmonics.

I am interested in verifying the output impedance.

If I understand the theory, when the output is terminated with a resistor which matches the output impedance then the power transferred to the load will be maximised.

I set about loading the output will a series of resistors and measuring the peak to peak voltage across them in order to calculate the r.m.s. voltage and hence the power dissapation.

Resistors of value less than 10 ohm gave strange results.

load r.m.s. power (V*V/R)
voltage

10 1.272 0.162
15 1.767 0.208
27 3.005 0.334
33 3.253 0.321
39 3.676 0.346
47 4.066 0.352
56 4.384 0.343
68 4.666 0.320
100 5.303 0.281

The numbers work reasonably well and point towards 50 ohms-ish.

The power value looks too high - so I might have made a mis-calculation somewhere!

Can anyone pass comments on the above?

I'm interested in where the 200 ohm figure comes from.

Any suggestions as to other methods of measuring the output impedance?

regards...

--Gary (M1GRY)

52. Drake R-4C and SB-620 scanalyzer

Did you have high levels of lead in your blood? The place I worked
sent the assemblers for routine blood tests, and never found anything.
We didn't have a wave solder machine, but we did have three reflow ovens
that were vented through the roof.

How true, how true!

I worked at Fairchild Semiconductor's Research and Development Lab from
1967-71, where we designed and built SYMBOL, a computer with a radically-
different architecture (OS, compiler, editor, etc., were all in HARDware
[and I do NOT mean ROM'd firmware; just lots and lots of gates and flip-
flops]). When we began actual construction, we tried to stockpile --
from Fairchild Semi's production line -- enough of every IC type we
thought we'd need, but we ran short by about 100 flipflops, so we got
three more "tubes" from Production.

It is safe to say that those hundred FF's caused us MORE TROUBLE than
the other 4,000 FF's: after two years of production, those later FF's
had so much FASTER "setup" time that our design rules failed when we
put those FF's and earlier ones on the same printed circuit board!

>the blades) or ....

Reminds me of a "Scratchi" article in an early ham magazine: a true
"HAM" (Hardly Any Money?), he made solder by melting lead and pouring
it into spaghetti and then tried to cut it with a pair of "dikes". I
still remember the final line of the story:

"Anybody want to buy a pair of badly-nicked sidecutters?"

--Myron.

P.S.: Please, no flames about Scratchi. Even though such stories aren't
"politically correct" these days, the anecdote in the above story
was timeless!

Well, I got the chance.

Worked marvellously. I now have that same 1300 foot range I had before.

Yeah, big deal, I know, but this is big for me - first "properly working", tunable, hard-soldered FM transmitter for me that can go farther than my bathroom.

Only problem now is getting rid of the 60-cycle hum from my homebrew power supply. Should be simple enough, and today I added the missing .1 uF electrolytic capacitor to the power terminals (was missing, don't know why I never put it in before). Still have the hum though. That's okay, this problem should be very well documented in the ARRL handbook. I'll go consult it.

I plan to revamp my cheesy little freewebs website - I'll be posting the schematics of things I built and found to be useful. This transmitter will definitely be among them.

As I understand it the output impedance approximates to Vcc*Vcc/Po, where Po is output power and Vcc is the supply voltage
It looks like your measurements point to 50 ohms as about right. How were you measuring the voltage? - this might affect the measurement

Not surprising. You want something *much* higher in value (a couple of
thousand uF).

Track down a manual as this will tell you what you need to know to hook it up, adjust it, and use it. For manuals, try Manualman or W7FG. They make good quality reproductions of vintage manuals.

I'd be interested to see the derivation of this.

>It looks like your measurements point to 50 ohms as about right. How were
>you measuring the voltage? - this might affect the measurement

I did the same thing (using different resistor values and then
calculating by V^2/R like the OP has done. It worked for me. The Zout
of my particular design was 140 ohms, though - just right for a folded
dipole. I used 2n3904 transistors; they appear to give a better gain
than 2n2222s.

As I recall, based on owning the TS680S some years back, the 140 does indeed have VOX. The 680 did not since it replaced the switch to use VOX mode with the preamp switch.
I think that the VOX mode switch is one of the small controls at the lower left of the front panel. The standard VOX controls (not jack) for gain, anti-VOX and delay should be on the back panel.

Hi guys,

If you are interested in a software which has more modes than you know what to do with, including Packet by the way, try out MixW by UT2UZ is really is excellent, and most modes are great for QRP.

The latest version 2.10 is on my web download page, and the help group is at Yahoo.

www.g3vfp.org/download.html

http://groups.yahoo.com/mixw

Lots of other softwares for radio use on my download page too.

Cheers,

Dave G3VFP.

71. Best antenna (preferrably wire)

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-03 18:38:59 UTC
From: Vaughn Combs <n2bha@arrl.net>

I have a few questions and I thought that this may be the group that could help. I have a nice sized backyard and would like to construct an antenna that would give me good performance on 80-10m bands.

The convenient dimensions would put a support (far end) at either 92 feet from the back of the house (support exists that is about 15-20 feet up) or 120 feet from the back of the house (mast anchored to the other side of a shed could easily be installed. Or a more inconvenient support could be erected up to 300 feet out (no support buildings) at the absolute far end of the property. The width of the property as seen looking out the back window is about 65 feet (no supports existing on either side).

Special circumstances and constraints:

-- No tall trees on the property.

-- Attic shack (attic window is probably about 25 feet up). Need to keep to the attic.

-- Cable run from back of house to operating position within the attic would be approximately 25 feet

-- MUST eliminate RFI in the shack and house.

My current setup is an end-fed longwire that works well on all bands except 40m (rig shuts down as I am dipping the SWR to almost 1:1 ;-). I threw up the wire as winter was upon me. I have been off the air for almost 10 years and REALLY wanted to get on the air again.

While the longwire is performing quite well with the exception of 40m I am getting a ton of RF in the shack and it is blanking out TVs and creating loud humming in speakers with 100W from the XMTR. I realize that this is most likely due to the fact that I have inefficient RF ground and I have cut and run radial at 1/4 wave for each band and ran them under the eaves up here in the attic. This has not solved the problem. I am friendly with all of my neighbors and have visited them and did testing on the bands with them on the phone. They are not experiencing any problems. My wife, while understanding, would REALLY like the problem to go away ;-)

My main goal is to build an antenna that will solve the aforementioned RFI problem and that will provide good performance given my constraints.

Any ideas would be GREATLY appreciated.

Many Thanks and 73,
Vaughn

Hi Vaughn,

Your first shot is probably your best shot. You should drop a line from the near end antenna anchor point directly down to a ground and rely on a tuner to make up the differences. From the anchor point (where both wires are broke out) install a 1:1 Current Balun (Choke) between these points and the transmission line back to your rig to eliminate some of your noise into the house, and to get rid of the 40M instability (a classic symptom of Common Mode whose cure is in the Choke). The "ground" lead will radiate, but that is inconsequential. You may also experience a ground loop with it in parallel to your rig's source of ground.

This is the blind-side of many hams who forget that long ground wires have impedance and thus become miserable grounds for RF. Unless you work battery operation without a floating charger, you WILL have this second path to ground (the 'trons will find their own way, even if it isn't obvious to you). I always run battery with a float charger through an 1:1 isolation transformer to kill Mains borne noise; and whenever I experience ground loops, I simply disconnect the charger.

To effectively avoid RF in the shack, the differential currents need
to be balanced (equal in magnitude and 180 degrees out of phase). It
is extremely difficult to do that with an inv-L. I had good luck with
a dipole even though the shack was under one end of the dipole. I
brought the ladder-line off at right angles for about 50 ft then
routed ladder-line back to the shack from there so ladder-line
parallel to the antenna was always about 50 ft away from the antenna.

Hi Richard,

If this helps both my XYL and I will be in your debt ;-)

So I should solder a shielded copper wire to the near end (aka the feed point but on the other side of the insulator --- near the house), let it run down the side of the house (about 22 to 25 feet down) and then to a ground rod? Then connect both the wire from the point where the new ground wire attaches and the wire (formerly the feedline) that connects to the "long" wire to the balun. Then its on into the house and the tuner via RG-8. Correct?

What do I connect to the ground lugs on the tuner and rig? The inefficient RF ground wire that I have now? That wire currently goes to a ground strip that has 1/4 wave length radials that were cut for each band running through the attic and an additional wire that is attached to a pipe that I found in the attic that is a plumbing drain pipe vent.

BTW, would there be any advantage to using other than 1:1 for the current balun? Any recommendations for the balun? I have seen some that can be made simply from coax.

I hope that I am not being a pain but this RFI prob is a bugger and it would be REALLY nice to squash this one. It is bugging the XYL quite a bit and it limits my operating time ;-)

Also, the ground loop that you are referring to would be current in the shield (or in my case the outer skin of the copper wire ;-) coming through the feed line and into the equipment. From there it is possibly getting into electrical ground through the power supply?

Again, Many thanks for your help and 73,

Vaughn, N2BHA

Yup. That is what I was describing, but it could work dangling (with
a sealed, insulated end that is mechanically tied down; however, this
is not anymore efficient as the floating wires along your rafters,
merely different).

View with fixed font:
BalUn longwire
rig --- tuner ant ---OOOOO-----------------------------
rig --- tuner gnd ---OOOOO-+
| |
| | drop
| |
----- -----
--- ---
- -

Ground loop issues arise due to there being two paths with a
significant distance (in wavelength) between them (from the +
down, through ground, and back up to the rig) and an impedance between
(the BalUn which serves this purpose by design). This usually comes
about when the ham shack is elevated, and still has some form of
ground return that is an appreciable distance (in wavelength,
basically more than 0.1 wavelength) from true ground.

The rig ground may be deliberate, or it may be passive through metal
connections and continuity with the power supply which in turn
inherits it from the wall socket. Even if there is no safety ground
from the wall socket, there is still a capacitive coupling in the

wiring to fulfill the mission (and 40/80M probably plays hell with the
VCR).

This may still be a viable option. Don't discard anything, simply
isolate one or all and experiment (it's the name of the game).

>

Simple coax chokes work just as effectively. Half a dozen to eight
turns of six to eight inch turns will be adequate for 40-15M, you may
need to experiment with a few more turns outside of this. Current
BalUns are simply Ferrite donuts put over a 1 foot length of RG-52
coax (one or a couple dozen donuts). The same thing can be achieved
with a large torus with four or five turns of coax through the center
(if its big enough). This is square law time, so four turns equals 16
donuts. Stacking two large toroids with 3 turns each would substitute
(or maybe three with three turns).

Using ferrite makes for a smaller device that works over a larger span
of frequencies, but winding air wounds can be tested immediately at no
more cost than the cable already handy.

Hi Vaughn,

I've described the ground loop above. Isolating it means "busting"
ground somewhere. I use a battery. Voila! Opening any path does
just as well, but you have a dangling radiator somewhere (like the
drop). This may help, or it may change nothing. RFI problems are
unique to every situation and having your shack up high is the major
contributor, but to keep peace in the family try to limit RF exposure

to the end of the pipe (the purpose of the choke).

The choke inhibits RF from traveling back (conduction) into your shack (but your rafter mounted "radials" contribute RF exposure through radiation). You might try wrapping your power supply AC leads through a ferrite (or use a split core). This is choking your rig from going into the House AC. If you do this, take care to observe ALL connections to the rig. Do you have a packet connection to the rig from a computer? This is another path to ground, Choke it!!! Do you have a modem on the computer? Ditto. Computer Display? Ditto. A powered microphone? Ditto. The shack is a hydra of wires all heading to ground eventually and all it takes is one - and sometimes it melts.

There are three forms of power transfer: Conduction, Radiation, and Convection. Clearly convection is out as we are not heating soup. Conduction comes through wire, and radiation through the air. Your problems (as for most) usually comes by virtue of shared paths in the AC distribution and this is a conduction issue. If you move your rig's power supply to another wall socket ON A DIFFERENT BREAKER, you might solve one problem (and discover a new one). Use an extension cord (choke it) to experiment with this possibility. Having the antenna feed point close to the house brings about the possibility of radiation coupling. Move it (the choke point) away from the house. Remember this is square law time too and with each doubling, you quarter your exposure.

Source record: 29764

If you want to obtain the maximum power transfer between a generator and a load, and if all the pieces behave like ideal linear components, then you need to match the impedance of the two. But this is not what you are doing here. First, you want to obtain the maximum power out without burning up you output device, and second, a class-C output stage isn't a linear circuit!

What this means is that in general your transmitter, like your wall socket, can deliver more than it's rated power if you put the right load on it. Normally you'd expect the final amplifier to be fairly "stiff" - the output power should be inversely proportional to the resistor you put on it. Your circuit doesn't act exactly like that, even if it doesn't follow the same curve for a generator with a linear impedance. I suspect that with your circuit the 7-pole filter is evening things out quite a bit. There's also a good chance that the "strange results" you see with a load below 10 ohms are the final amplifier going unstable and oscillating, or your output transistor heating up and changing characteristics on you.

So what it boils down to is that it is very important that your output stage _sees_ the right impedance, but you shouldn't expect the output stage to _deliver_ the same impedance that it needs to see. As long as you're getting power out and your output transistor isn't letting all the smoke out then you're fine.

The 61-1060 wall wart type (and its more expensive 7 day big brother)
won't click, because the relay board is powered by the AC plug, but
the timer is on a seperate board with only two wires between it and
the relay board. Easily hackable, IMHO. (Replacing the click dome
pushbuttons with tact switches is recommended, too).

There's an article in the December or January QST about using a laser printer to make labels. Basically you design your whole front panel and print it out on a laser-printer compatible transparancy, then stick the transparancy onto your project. If you're doing it at work and can't make sure that you'll get to the printer in time to feed it the stuff, you print it on white paper then copy it onto the transparancy.

Office supply and art stores carry the stuff, but the art stores have a better selection.

I used to work at a place that made front panels that way on short runs of commercial equipment -- you do the laser printing on one sheet, then carefully apply another clear sheet over that (and accept the rejects when you get wrinkles and bubbles). The result was not distinguishable from a professionally made label, and didn't require the $$$ for setup from the commercial label houses.

Yes there were bad things going on with very low value loads, the output was collapsing and re-establishing. The srtange results may also be caused by the loads with were high wattage resistors - no idea what inductance they might have had.

> So what it boils down to is that it is very important that your output stage

So perhaps the fact that the transmitter is connected to a 50 ohm load and the output transformer is 2:1 turns ratio means that the transistor is "seeing" 200 ohms?

Nevertheless I am still interested in how to verify that any circuit which I design (copy!) does have a 50 ohm output impedance. There must be some way to verify this figure.

>

Vcc * Vcc / Po = 13.8 * 13.8 / .352 = 540 ohms (for a 47 ohm load).

This value is certainly in the right ballpark.

I guess that I should also measure the current taken by the final stage and see if this ties in too.

I connected various 1/4w resistors across the output using a couple of adaptors, but being aware to keep wire lengths as short as possible. I then simply used a scope probe and scope to make the measurement. Scope probe was a standard x10 10Mohm impedance and presumably small C.

Interestingly I was surprised at the magnitude of the voltages for such a tiny power.

regards..

Both AF and HF power amplifiers generally have a very low output impedance.

Motorola's AN721 app note on impedance matching networks for RF
transistors explains this.

This doesn't apply to QRP output stages, though.

Hi, Leon,

Do you know Brian (G4BCO) by any chance?
My - admittedly little - understanding of the situation is that the
power transferred into a resistor (regardless of power level) will be
maximised when Rs=Rl,. whereupon half the power is dissipated in the
final device and half in the load. Tim's posts seems to refute this
basic truism. Clearly the statement that the output power should be
inversely proportional to the load resistance *must* be false.

No, that isn't the case. From AN721:

"The load value is primarily dictated by the required output power and
the peak voltage; it is not matched to the output impedance of
the device."

No just leave the mic plugged into the mic jack on the front and push the VOX button in. Then adjust the 1) VOX GAIN, 2) DELAY, and 3) ANTI-VOX so that the radio 1) begins to transmit when you speak, 2) stops transmitting shortly after you stop speaking, and 3) doesn't trip on background noise

I was thinking my next project might be some sort of 'device' that I could put in the car.. Drive around and have a message sent back every few seconds with GPS and signal strength measurements. It would be great for testing our local repeater or antenna system. I was thinking of using something like APRS with a A2D converter to translate the signal strength from a HT. Then formulate a packet with GPS and signal strength and blast it back to a base station or just send the data to a laptop. I know there are similar commercial 'devices' for cellular and CDPD. But was wondering if any one knew of a device for ham radio use? Anyone know any devices that do something like the above or articles or schematics?

Source record: 29783

Hello,

I have a general question regarding tuning diodes:
Does the oscillation voltage alter their capacitance, or is capacitance a slow changing value - like resistance and PIN diodes?

The reason I ask is that I am spicing (simulation) a VCO I wish to build (wide range 140-240MHz) and get an oscillation voltage of 20 volts peak (maybe the Q is too high). This high oscillation voltage would easily swamp the tuning voltage, 3-15 volts, and forward bias the diode itself.

If anyone wishs to reply directly they must remove the "xxx" from the return address or write to:
james dot fenech at nec dot com dot au

Thanks,
James.

Source record: 29784

OK, my point is (and you can test this yourself), that (1) the concept of Rs is invalid for a class C stage, because it's not a linear device. You can fool yourself into thinking it is, but it's not. (2) the typical RF output stage, sans output filter, which consists of a transistor fed by a choke or transformer and which pulls the collector voltage nearly down to the emitter acts like an RF voltage source with a fairly low series resistance. I've _done_ this. I've _measured_ this. I've _burnt_ transistors.

You _can_ get much more power from your output stage than it's "normal" output power, for that brief (and often shining) moment before the output transistor lets the smoke out and reverts to the sand and basic petrochemicals from which it was originally made. This is how you know that you aren't running it at the Rs = Rl point -- rather, you're running it at the point where the junction temperature of the transistor is kept to a level that will let it stay a transistor for a satisfying amount of time.

This is why in my original reply I compared the output amp to a wall socket. The equivalent Rs of your average wall socket is probably on the order 1/2 to 4 ohms (on the low end for 120V, high for 230). Since I live in the US and have fairly good feed, I'll use the 1-ohm 120V case, and I'll match Rs with Rl. Lessee. 120V, 1-ohm, that's 14400 watts -- good! But my circuit is only is only good for 15 amps and I'm asking for 120?!? Dang! What happened to the lights?

So you see, every time you plug anything into the wall, you're failing to match Rs with Rl, and that's a _very_ good thing. It's for exactly the same reason that you don't match Rs with Rl in your output stage.

Please see my reply to Paul Burrage in the next branch over -- hopefully I'm clarifying that for a power output stage you _don't_ want to see matched impedances.

For a stage (such as an intermediate, class A stage) where you _do_ want to verify the output impedance you can either find the resistance _and reactance_ that maximizes the power output, or you can build an RF impedance bridge (I use a noise bridge) and measure the stage output impedance directly. Just don't let it break into oscillation on the output of that poor impedance bridge!

Source record: 29786

Here's an experament: Build a power output stage _only_. Don't put a filter on it. You should have a transistor with the emitter grounded, a choke to +12V, and some minimal network on the base to keep it biased. You should be able to pick this out of your Tuna Tin II design. Capacitor couple an appropriate resistor to the collector (200 ohms if you use your Tuna Tin II).

Now feed it with enough RF so it's really into class C, and measure the RF voltage on the resistor. It should be around 8V (supply * 0.35) give or take a bit.

Now change the output resistor by a factor of two and measure the RF voltage again. It should be about the same as before assuming that you've sized your choke correctly (4x the design resistance). This shows that your output stage is stiff (i.e. has a low equivalent Rs).

What this all means is that your average well-designed output stage does _not_ have a matched Rs! Why? Because when Rs = Rl the power in Rl is maximized _for that Rs_, but the power burnt into heat inside of Rs is also maximized! Since you want the power in Rl to be much higher than the power used to heat up your shack (unless it's really cold inside) this is a good and desireable thing.

The varactor capacitance change is instantaneous -- think of a capacitor who's plate spacing is dependent on it's voltage. This is why varactors are used for frequency multiplication -- that capacitance change "squeezes" the pulse to generate lots of harmonics.

So your oscillation voltage will certainly affect the tuning, and the forward bias effects will be most unfortunate.

I have modelled varactor diodes by dinking with the area parameter of the SPICE diode model, but I'm not a pro in that regard and don't know the "right" way to do it. SPICE is also not the tool for determining the behavior of nonlinear high-Q circuits (I believe the best tool still involves FR-4 and lots of cussing).

As I understand it, the oscillation voltage does vary the varactor's
capacitance, and that's the reason that lots of VCOs have a pair of
tuning diodes connected to opposite halves of the tank. It's still
good to keep the oscillation voltage small compared to the tuning
voltage.

Yes, the RF generally does cause nearly instantaneous voltage changes, and therefore capacitance changes, across the diode. Spice should handle this properly. You need to lower that RF voltage! In addition, the average capacitance will depend on the amplitude of the RF because of the nonlinear nature of the capacitance versus voltage, so it's important to keep the RF level reasonably constant, for stability. It's fairly common in covering a wide range, especially if you also want low phase noise, to break it up into subranges which might be selected with switching or PIN diodes. Of course, it's also critical to keep the control voltage "quiet" because at 10MHz/volt or so, a millivolt will give you 10kHz of frequency deviation.

If you look up other uses for varactor diodes, you'll find that the characteristic you are asking about is used to make efficient frequency multipliers, and even mixers and amplifiers. (Search for "parametric amplifier.")

Cheers,
Tom

Rubbish. Varactors are not used for freqency mulitplication. They are
freequenty used in VXCOs for modulating (or otherwise varying) the
oscillator output frequency by means of applying a DC bias voltage
which alters the capacitance of the PN junction.

First, can you do us a favor and stop the constant cross-posting between these two newsgroups? Take note that the original post was only to rec.radio.amateur.homebrew but for some reason you felt it necessary to cross-post your reply to sci.electronics.design.

You've also shown your age in claiming varactors are not used as multipliers.

You only have to look at ham magazines and books from the early sixties to know that frequency multiplication was a common use for varactors back then. Get a power varactor, and you could get onto a higher band by feeding it with a high power signal. An easy way to get on 432 or 1296MHz without any amplification on the signa frequency.

It's hard to judge these things, but it seems like for hams, multiplication was a more signifant use for varactors in those early days than as a variable element in an oscillator. After all, FM wasn't that common in the early sixties, and a VCO was fairly a novelty. Few bothered with PLLs of any kind, and for a free running oscillator with no small frequency counters, one was better off sticking with a variable capacitor as the tuning element.

Of course, another common sight back then was to see varactors in parametric amplifiers. Though those saw relatively small use in ham radio, in certain areas their need was much more useful than a VCO. Actually, there would have been a fair amount of overlap between varactors as multipliers and varactors as small signal amplifiers, since hams needed them at the higher frequencies if they wanted to do weak signal work.

Your own rubbish, Paul. In truth of fact, varactors are nicely used
for frequency multiplication, just as Tim stated. They also work well
for VCO FM modulation, but users must keep in mind their instantaneous
capacitance-change property and be careful to bias them in appropriate
higher-voltage bias regions, or risk unintended distortion. When used
as multipliers, low-voltage bias with large signals enhances the effect.

Thanks,
- Win

If you are determined to be arrogant, it helps to occasionally be
right. Varactors are still used for frequency multiplication. They
were also commonly used as parametric amplifiers and mixers before
other semiconductors got fast enough to work at microwave frequencies.
Varactors were even used as paramps in the front ends of opamps.

Google "varactor frequency multiplier" and "parametric amplifier" and
maybe learn something.

For what it's worth, National Semiconductor's resident wizard Bob
Pease used to clean circuit boards using an ordinary dishwasher and "a
standard charge of Calgonite". If I recall correctly, he suggested
taking the board out after the rinse cycle, doing a final rinse with
distilled or deionized water and then shaking the remaining water off
of the board prior to air-drying.

He reported that this method would get the cross-board leakage
currents for sensitive high-impedance circuitry down below what he was
able to achieve with organic-solvent washes.

Google"varactor multipliers", still used. Popular technique in
the 60's for getting 70 cm output from 2m TX.
As osc control keep RF across diode low, high levels produce harmonics
and reduce tuning range. Most tuning varieties have max V = 30.
At low freqs power diodes work ok and have high V rev.

I started repairing the Collins/Rockwell receivers in self defense. They decided that we had to rent a loaner from them, or they wouldn't repair our equipment. They charged $150/month rent, and took over six months to fix a receiver. The typical bill was over $1200. I had the manual, so I popped one open and found the first LO was fried. Rockwell told me the microwave transistor was 1500, minimum ordered of 18 parts because it was out of stock. The transistor was a die mounted to a gold stud, and covered with a drop of epoxy, and no part number. New Microdyne LPR receivers were right at $1000, and worked a lot better so I told them to forget it, that we were going to repair what we could, and replace them with the LPR units, when we had to. I fixed most of them in under one hour bench time, and less than $20 in parts. The biggest problem with them was they ran way too hot, and over a five year period, the circuit boards developed a large black spot in the center of the board as they cooked themselves to death. Still, it was my first work with solid state microwave equipment.

I found a VCO board for a Microdyne synthesizer in my junk the other day. They had used the design for years, and it was becoming harder for the techs to get them to meet the specs. I was asked to work on them for while and found a number of problems with the design, and parts that were selected to replace obsolete parts. I learned a lot of tricks to clean up a PLL circuit fixing a mountain of rejected modules. It was harder work convincing both design and manufacturing engineering to correct the problems, than it was to find the problems.

Paul, please look over my various posts on this issue and tell me where I failed to point out that you can get more power from a bare RF output stage by loading it differently.

I'm gonna go fertilize my garden!

I don't see why not, although getting the data rate high enough to transmit audio in real time might be tricky. Assuming heavily compressed (not hi-fi ;-) audio at 8kbps, you have 125 microseconds to send each bit. Some googling suggests that 10 us jitter in spark timing is achievable with a mechanical (rotary) gap. You could use on/off modulation or perhaps even pulse-position modulation. Perhaps you could use a UV flash to reliably initiate the spark at a particular time, or a secondary spark. You'll have to connect the digital electronics to the spark-gap transmitter somehow.

Several years ago ARRL marketed a WIN3.xx software package called "Radio Designer" which was a 'lite' copy of a commercial RF design program. Unfortunately the program does not run under 16- and 32-bit Windows environments, and the OEM is not interested in entering into further arrangements with ARRL.

Does anyone know of a similar program in a price range (under $500) attractive to hams?

The company that made ARRL Designer (Compact Software) was bought by Ansoft.
They have greatly enhanced the capability, and the current offering is
available as a free student version here:
http://www.ansoft.com/ansoftdesignersv/
There are also many other evaluation & student packages available on the net
for free. Check out this site as a starter:
http://www.rfengineer.cc/rftools.htm

Also, if you do an internet search on "RF circuit analysis software" or
something similar, you'll get lots of hits.

BTW, I run ARRL Designer under Win98SE and it's fine. What OS are you trying
to use it with?

Hans,

ARRL's Radio Designer Version 1.5 (copyrighted 1998) claims that it runs on both Windows 9x amd NT systems, and I can confirm empirically that it operates on Win XP Pro as well - an excerpt from the included Help file is below:

" ARRL Radio Designer 1.5, a Windows (3.1, 3.11, 95 and NT)-based computer program, lets you create computerized models of audio, radio and electronic circuits so you can see how they work--and make them work better--without actually building them....."

IIRC correctly, the last version sold by the ARRL was 1.51. If you are using an older version, perhaps you can find a copy of this one somewhere? Was originally $150, should be a copy at a fraction of that out there now that it is discontinued.......

>a great loss really...

Larry, I have been buying electronic components from Radio Shack for 40 years, and I can't say I got any that were complete c***. They all worked, isn't that what you get them for?
Radio Shack doesn't manufacture any of the parts they sell, they repackage OEM parts and resell. They cost more, and the people working there know little or nothing about the parts section. But the parts work.
As another poster pointed out, they are mighty handy for the odd part to meet some deadline, or if you are just trying to finish your latest weekend creation and need a 1N4007, and a 10k 1/4 watt in a hurry. I would never use them as the major parts supplier for anything but the smallest of projects. I would consider them getting out of the parts business a loss.

Well, you're objecting rather strongly to an assertion that I never made. In theory if you want to get the maximum available power out of a generator you _do_ match it's output impedance. In practice if you do this with most RF final amplifiers you will reduce your final element (whether transistor or tube) to slag -- that's why modern commercial radios have SWR protection circuitry.

Please see my reply to your post starting with "Hi Leon" for a full explanation, and please actually read it before replying. Remember also that everything I say (including the attempt to match output impedances with the wall socket -- I was only 8 but that's no excuse) has been backed up by experament.

APRS allows sending short messages. One way is to format the signal
strength readings as ASCII and insert them into the proper place. I can't
give information. APRS also is set up for DF bearings and signal strength
values.

hi there..

think i will put my pennys worth in here...

do away with the long wire altogether..you will proberly never get rid of
the rf in shack etc..due to being too high above gnd..i know i have tried..i
live in an apartment (3rd floor)..no garden or land..i have tried end feed
long wire from balcony to lamp post etc..rfi to phones stereo etc..BAD

i tried all the tricks in the book no go...
SO.. i chatted my neighboors up and have been using successfully for 4 years
now a full sized 10m-80m diople (trapped with 40m trapps.)its slung up at 3
points in the shape of a triangle each courner on someone elses
apartment..the coax feed is rolled up 6 times 6inches dia just before diople
feed point..i have hung seperate dioples for 18mhz.28mz below main diople to
help on those bands ..
i have had NO tvi/stereo i/ phone i etc atall (touch wood)..i am using full
size diople but not out straight so you could too, espically as you have a
garden!!!
and have worked much dx all over the world with 100w ssb...

so if you give up with the long wire (as i did) try this..its cheap too..and
the antenna is in about every antenna handbook..)

My understanding is that the Rf Designer program from ARRL has a moderately complicated user interface and so it was not quite a popular as originally hoped.

However, the Ansoft student version is just about as capable if not more so and is a bit easier to learn.

http://www.ansoft.com/ansoftdesignersv/

==========

A long time ago I ran across a free S parameter simulator, RFSIMM99, which handles most of the things I need. It also has a monte carlo tolerance analysis which is convenient when I want to see what component tolerances are going to do to me.

The company that originally made this program seem to not be there any more, or at least my link to their website does not work, but the program can be found on quite a lot of websites.

Always begin with the most simple of antennas. Otherwise you'll have
nothing to make comparisons with. You will have no base or foundation
standard.

Spend a couple of hours stringing up a 150 feet inverted-L and use it on all
bands for a few weeks. That is if you can wrench youself away from it.

Does anybody know of a site where I can cross russian transistor numbers over to american? I can probably guess at a replacement since they are small signal transistors. The transistor numbers are KT315 and KT361.
Thanks, Rob

Okay, so if I understand you correctly you're saying that whilst you
should try to match impedances in Class A; it's inapplicable in Class
C? It's just an operation class distinction?

Hans,
I found that it crashes with certain video cards. The reason I originally took it off my Win98SE computer is that it would just lock up with a scrambled video screen at startup. Some time later I upgraded my video card and on a lark I reinstalled the program. It's been working fine ever since.

Henry, your ventilation on the wave solder machine is all wrong! If you need to look into it, therre is no way that the vent air pull should be past your face. That thing should have a side plenum vent. the fouled air will then not make it to you when you look in it.

> As has been stated, the fumes are from the flux, and I have inhaled a bunch

> I am sorry you had health problems, but it may not be for the reason you

If rosin based fumes are bad for you, than I get a double whammy, since I make telescopes too, and the polishing laps are made out of pine pitch. Between that and the soldering rosin, my garage always smells like pine. Yummy!

Sorta. The distinction has more to do with whether you're following your output stage with something that needs to see a specific impedance (like a filter in a receiver), and whether you're building a power stage. I couldn't think of a good generalization, so I listed some examples below. Then I realized that it really boils down to the fact that the impedance matching rule is a tool for predicing circuit behavior, not a guideline for life.

RF stage in a receiver: you want to match the output impedance to the following filter or mixer for maximum power transfer and good filter/mixer performance. You usually _don't_ want to match input impedance because the best power transfer impedance is not the same as the best noise figure impedance.

IF preamplifier (between a passive mixer and a crystal or mechanical filter): Match both input and output impedances, both to maximize power transfer and to get good performance from the attached stages.

1st buffer in a VFO: _don't_ match impedances with the oscillator! You want to purposely refrain from taking much power from the oscillator tank, because a heavily loaded oscillator is a poor oscillator. You probably _do_ want to match impedances on the output so the following stage won't need so much gain.

1-transistor transmitter: It's an oscillator, but a power stage too. Load it (match impedances) enough to get useful power on the antenna, but not so much that you screw up performance.

Power output (usually): match impedances to the input, don't match impedance to the output (for all the reasons given earlier). This applies to any class of stage: A, B, AB, C, D and E (yes, there are class D and E stages).

I hear you. I have several older (DOS) comm programs which puke on
faster machines - good ol' PCPLUS for one. That's why my 24/7 packet
circuit (for the local ARES/RACES group) runs on a separate (166
P1) machine - it slows down my Athlon XP 2000 and my P2 machines.

I'm trying to find a DOS emulator for Linux to see if I can run two
circuits at once now...,..

A version of F6FBB is available which runs native on Linux, using the
Linux AX.25 networking support code. There ought to be no problem
running multiple TNCs (either real ones in KISS mode on serial ports,
or soundmodem versions), doing digipeating, etc. on Linux.

I think it was after last summer that I saw a published magazine article where someone had come with a new way, at least for me, to align a radio so that the dial would be calibrated throughout its range. IIRC he set the trimmer, padder and other adjustments just once or maybe twice. In the past I have set and reset all adjustments several times, each time cutting the error in half until I'm satisfied or worn out.. If anyone recalls the article I sure would appreciate knowing. It seems like it may have been Monitoring Times or Popular Communications, neither of which I subscribe to, but it could have been elsewhere, because my memeory isn't as good as it was because I was taking Lipitor, and have now quit.

Hi All,

thanks for the many responses. My use of this VCO if for a homebrew spectrum analyser, 0-100MHz with a 140MHz first IF. This sort of rules out doing it in ranges - maybe?

I'm only an RF beginer, and spicing the circuit gives me "some" confidence that it may work, but I understand that spice may be quite a bit off the mark with parasitics and all.

The idea of reducing the RF voltage across the part is a good one, but how do I do it? I am actually using two in series (back to back) but 20 volts peak seems a bit much.

I have the ARRL handbook (1997 or so) but this doesn't have much in the way of theory. Is there any other reference anyone can recommend?

I could just build it and see if it works, but I wouldn't be able to test much except measure the operating frequency.

James.

163. Misc transformers/supplies offered

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-06 22:56:59 UTC
From: Roy Brock <roybro@sccoast.net>
Message-ID: <btfeqb$768v$3@news3.infoave.net>
Source record: 29650

Back several years ago, I picked up a bunch of used transformers. No time for the projects now, and can't bring myself to just throw them away.

Most are low voltage, high current (>8A), but I also have 2 Advance Transformer catalog # 09-141-21. These are 208/240 volt primary, 1900 volt secondary, 3.0 kVA units. They were used in ceramic capacitor breakdown testing (voltage doubled to produce 4100 VDC).

I have another that has dual 120-volt primaries and two secondaries: one 450VAC@ .54A RMS and one at 1825VAC@ .44A RMS.

I also have some Power-One open-frame DC supplies, regulated and unregulated. Email me with what you are looking for, and I'll let you know if I have it....Roy Brock

Motorola's first solid state 450 car phone, the MK, used a 50 W 150 MHz PA followed by a varactor tripler for 10W at 450. Varactor triplers are tricky however.

I highly recommend _Experimental Methods in RF Design_, by Hayward, Cambell, and Larkin. It's published by the ARRL and available from them and numerous other sources. Besides theory and a lot of real, practical, tested circuits and projects, it includes simple test equipment you can build yourself.

I have a 3/4 or perhaps 1" CRT. Possibly from a camcorder, don't know. Haven't been able to find anything. The wearable computer sites may be a possibility, but I didn't see any leads so far. I want to use it for a portable DF system.
The number is unreadable. It has yellow ink printing not etched. What could be the manufacturer: an "N" followed by what looks like a backwards somewhat stylized "B" What there is of a number looks like R2 then possibly a 1 and most likely a 5. So it sort-of looks like R215, but much of the ink is gone. Standard 9 pin. Pins 4-5 must be the filament since they show 4 ohms cold. about 1" dia & 2" long. How about some ideas???

Phil,

Don't know if it will help, but how about this:
http://www.dosemu.org/
I have no idea if it will help or not; I'm thinking of putting Linux in one of the boxes. A Google search of 'DOS emulators for Linux' yielded a ton of hits, but you've likely already researched them.

I've got one of these that runs the motor one way for "on" and the other way for "off". Add a microswitch that follows the valve position and you've got it! The timer in question runs off 2 "C" cells and is programmable for "time on" and "duration". Made by Melnor (sp?), large distributor of lawn/garden accessories. Probably available from others.

Much Luck!

If it is from a camcorder, it should have a deflection yoke. How
about some pictures? It might trigger someone to recognize it.

Suitable newsgroups are:
news:alt.binaries.schematics.electronic
news:alt.binaries.pictures.radio

Also, you can lay small parts on a flatbed scanner, cover them with a
sheet of white paper, and put a light over the paper to reduce shadows.
Yo can get good close-ups this way. I usually scan at 600 DPI, and
reduce image size to what I want. I would post a picture, an ask the
guys on news:sci.electronics.repair if anyone there can identify it.

Thats a good idea. Also consider if the timer reverses the motor it could also control a polarity sensitive latching relay or a common dual coil latching relay with steering diodes.

I have used Melnors in the past for watering, they tend to short out internally due to moisture. I kept Melnor busy warranteeing those things. Of course for this purpose it would be ideal. I had ones with a 7 day schedule. Pretty neat...when they worked!

Once you get it as close as you can, you can bend the plates of the
air variable. This will align it in little band segments. Remember,
the slug will align the low end of the band, then you can use the
trimmer to touch up the high end, without much effect on the low end.
Also, on older equipment, Ive found that sometimes you cant get enough
induction out of the slug/coil. I think the slugs lose density over
time, so you may end up rewinding the coil with a few more turns of
wire.

178. need household-substance anti-static coating for plastic meter cover

situation is a plastic meter cover, on a large process control board, onboard a tanker ship, deployed. The meter movement underneath experiences wild meter-swings, associated with finger contact, presumed to be due to static electricity.

we have a decent collection of household-type substances, also a small collection of industrial substances.

we have infrequent but regular access to Navy Exchanges, which are basically transplanted K-mart sort of outlet. Carries common american brand-name stuffs.

The official Navy Supply Chain can deliver almost anything, but not always within your lifetime.....

On a vintage 1994 PC with a Windows 95 upgrade, where do you look to see if a sound card is installed? Inside the cpu or somewhere in the control panel? Both?
If you just have to check in the control panel (Hardware Profile?) what would be the designation for it?

Thanks,
KB2AMY

Alan Horowitz:
A common liquid dish detergent like Joy, Palmolive, or Dove applied with a soft cloth or very soft paper towel like Viva (do not add water)..... wipe on and then wipe the excess off..... I have been using this method for decades on plastic analog multi-meter faces and it works great and has lasting effects.

Clean it with liquid "fabric-soft" meant to be used in washing machines (the pink goo) and then wipe it with one of those "static-free" sheets you use in the dryer.

Use caution and a FEW drops of the pink goo so it doesn't run into the meter bearings and gum things up.

How big is it? If not too big, just breathe on it. The moisture in your breath will take the static charge away. Or you can just wipe it with a damp cloth. We have VU meters in audio that do the same thing. But most level meters now-a-days are solid state plasma displays or LED's.

186. Anyone willing to contribute an old Handbook CD?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-07 20:02:39 UTC
From: Lenny Wintfeld <lennyw@comcast.net>
Message-ID: <MPG.1a662fe73eb4256b989687@news.nj.comcast.giganews.com>
Source record: 29672

Hi,

A new friend, Ciro, CO6CR, who I recently met on 14070 psk asked me if I have an old copy of the Handbook CD. I don't, but I promised him I'd ask around the newsgroups.

If someone has an old Handbook CD they'd be willing to part with, I'm sure Ciro would be very appreciative. He's currently using a '70s vintage German made rig that was designed for 40 meter operation. He modified its PLL for 20 meter operation without having a schematic! A pretty resourceful fellow.

His rig produces no psk output at all with low audio drive, and then when it finally does output, it has an IMD of -8 or higher and 3 or 4 visible sideband pairs. I'm sure he's looking for a way to improve this situation.

Anyway, if you do have a Handbook cd you can part with, send it direct to him at his QRZ.COM address, or send it to me and I'll forward it.

73,
Lenny W2BVH

187. Rig to PC interface with TS-140s?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-07 20:03:31 UTC
From: fazamy@aol.com
Message-ID: <20040107150331.19282.00002359@mb-m13.aol.com>
Source record: 29674

Can the TS-140S be linked to a PC? I have little info on this subject. I heard about the IF-232C interface and the RS-232 serial port. But I need to hear from anyone who has linked his TS-140S to a PC.

I have a bunch of projects in mind, now that I have the time. That's why I've been doing a lot of posting :)

Thanks,
KB2AMY

Yup, works for me. I use it on my monitors and my TVs. Help reduce the
dust buildup on the surface also.

Hi Roy,

thanks for the suggestion. I am considering buying this book. Can I ask how much theory, and how deep does it go? I am an engineer (digital electornics and software background) and actually like some theory to help me understand what I am doing.

I already have some "real" test equipment, 50MHz CRO, signal generator, multimeter, etc. So "simple" test equipment may not be too much of an improvement.

I've looked over the internet, and some books that I have, but found no real example circuit on wideband VCOs. The only "sort of close enough" circuit I found is at:
http://www.newwaveinstruments.com/resources/rf_microwave_resources/sections/oscillator_vco_theory_design_circuit.htm#Voltage%20Controled%20Oscillator%20(VCO)%20Circuits
The second one down - Colpitts. Are there any such examples in this book?

Thanks,
James.

You're climbing a steep hill here James. It is the % change in frequency that is the problem. Professional spec analysers use a 2 GHz LO with a 2:1 range (to scan 0-2GHz), but I believe that is a magnetically tuned YIG resonator. If you could get the frequency higher, so the sweep range is narrower, then mix to the desired freq with a balanced mixer...that would be an easier VCO design.

2:1 tuning range with varactor tuning is very doable in the frequency range he's considering. I've done 3:1 at lower frequencies. No steep hill at all.

Thanks Joe,

I wouldn't have thought it would be too difficult. Minicircuits sells parts that have a 2:1 range (not the right range though), and I only want 1.7:1 or so. Interesting idea about downmixing, but I really don't want another mixer and oscillator in this thing.

Acording to my pspice results I can get the range, but I'm a little concerned about the high voltage swing on the varactors causing very poor phase noise.

James.

James
In general, very wide tuning range and very good phase noise are sort of antithetical. If you use the circuit I sent you, the phase noise will be quite good for your simple spectrum analyzer application (unless you're planning to have a very high resolution/very low bandwidth mode).

Don't get too hung up on your Spice modeling. It can keep you from trying some things that are known to work. In general, if I can build it faster than I can model it, I'll just go right for building it. I use modeling to get another perspective, but not to get the whole picture.

Seems to me I read a note about W7ZOI starting to build a variation of his original spectrum analyzer which will cover up to 200 MHz.

http://users.easystreet.com/w7zoi/vhfbpf.html

He expects to use a mini-circuit VCO.

POS-535 VCO from MiniCircuits will sweep from 260 to 460 MHz

Given a first IF of 260 MHz, it all works nicely.

Personally, I'd be inclined to do something like this, using the minicircuits part, since they tend to be fairly linear tuning MHz/VOLT which simplifies the sweep circuitry a lot.

I have built broadband tuning range VCOs before, and I know it can be done, but in a spectrum analyzer, the performance is usually limited by the first VCO so using a good performance VCO makes sense to me.

>
> Not surprising. You want something *much* higher in value (a couple of
> thousand uF).

I posted an additional 80 lines or so in reply to this, but whether my ISP or my newsreader is the device that's screwed up, I don't know. Getting very irritating though, that every time I spend more than 30 seconds typing a reply it farhques up.

Anyway...

Between the full-wave bridge rectifier and the regulator is a pair of 35-v 1,000 uF electrolytic cylinders. I considered using a 4,700 uF, but it only sports a 16v rating (even the pair I have are only 25v). I did put it in parallel to my radio on the outside of the supply, and it /seemed/ to help some, but I'm tired and didn't take notes. I've played with different voltages as well, and it seems worse at higher voltages. Thinking it might be that there is no load on the supply, I added about 300 mW (it's a 450 mW transformer) of a light bulb to the mix. Didn't help a bit, and really heated the regulator up rather quickly.

I don't expect the circuit to be perfect, in spite of how I "sound" when I look back over what I've typed. However, I know it's got to be incredibly simple to fix.

Having forgotten what I typed this morning, and being irritated by how today has flown right by and I have accomplished close to nothing, I'm signing off soon and going to bed. Thanks for your suggestions, and I've got some research to do on the matter this w/e.

Experimental Methods is oriented toward the advanced amateur, so you won't find the depth and level of math you would in a college text or a specialized text on one of the many topics covered in that book. However, there's a lot more depth than you'll find in something like the _ARRL Handbook_. Another thing is that the authors are all experienced and professional engineers who've spent years doing RF design, and all know a very great deal about the covered topics. In my opinion, only someone with a very deep and basic understanding of the fundamentals can accurately explain theory in an intuitive and easy to understand way. The authors have that understanding. I have no doubt you'll be very pleased with the book.

Re test equipment: how about devices for measuring RF power, impedance, frequency, inductance, capacitance, Q, spectra, noise figure, and crystal characteristics?

I don't believe there's an example of a wideband VCO. The authors concentrate a lot on keeping phase noise low, so use other methods to achieve wideband operation than with a wideband VCO.

If you're looking for a more theoretical treatment of oscillators and other RF circuits, I recommend Hayward's _Introduction to Radio Frequency Design_, now also published by the ARRL. (You might find a used first edition, published by Wiley as I recall.) After reading the chapter on oscillators, you'll know enough to get a good start at least at designing your own VCO.

There are a lot of practical tips and observations about oscillators in _Oscillator Design and Computer Simulation_ by Randall Rhea (Noble publishing, ISBN1-884932-30-4), although in my opinion it doesn't convey as fundamental understanding of oscillator operation as Hayward's books.

Reminds me of the time I did some radio work on four RCL cruise ships.
They each had a very impressive instrument panel in the engine room. On
every one of those panels was rigged up a simple plumb-bob on a three
foot string. I guess the engineers didn't put a lot of faith in the guages!

See my spectrum analyser:
http://www.hanssummers.com/electronics/equipment/spectrumanalyser/index.htm
which has 145MHz 1st IF and covers right up to (and through!) the 1st IF,
using an SA602 VCO covering 145MHz to something like 300MHz with no problem
and apparently excellent linearity. The varicap is BB105. Dynamic range is
limited to something like 70dB by the choice of front end (SA602) but it's a
fun and useful project that is quite easy to build. If anyone wants the
circuit diagram and full construction details let me know.

I think there may be two topics here....are you looking for the
interface that will allow you to control your radio with software on
the PC, such as software to do logging, frequency and mode control,
beam direction control, logging, etc., or are you looking for an
interface to allow you to operate with soundcard software to get you
on PSK31, RTTY, slow scan TV and other digital modes?

The IF-232C interface may have been discontinued by now. The good news
is that you can construct your own interface with a MAX32 IC, and a
74LS04 IC for about $4.00 plus a little box to mount the circuit in.

If its a soundcard interface you're looking for the Rascal is a good
choice as is the Tigertronics or Rigblaster. And there are a number of
other good ones out there too. It all depends on how much money you
want to spend.

What exactly are you trying to do? The TS-140 is new enough to be
computer controlled easily.

My comments are colored by experience desigining quite low noise, relitavely narrow bandwidth VCOs, so all the other comments are very valid.

I will note that there are two aspects of noise to consider, that I can think of off hand. One is that:
1) Too low of an absolute DC voltage on the varactors will make for a noisy VCO and
2) A wide tuning range means that the varactor is relatively tightly coupled into the oscillator which means that control line noise/spurs you'll have to watch control line noise & spurs.
3) This also means the Varactors have more effect on the oscillator Q and therefore can also mean increased noise.
OK nobody expects the Spanish inquisition.

If you can determine the actual noise performance and keep it in mind that the analyzer has a noise limit, you'll be ok.

Been away from it too long and can't seem to recall why we used to use two, back-to-back varactors...brain is full...seems like it was to reduce the voltage across the varactor.

Message-ID: <b2nLb.472$sU2.451@nwrdny01.gnilink.net>
Source record: 29695

Steve,
I think the main reason for back-to-back diodes is to prevent rectification of the RF. Rectification can cause several bad things, including pushing DC current back out the tuning voltage line, instability, and increased phase noise. Having said that, I tried back-to-back diodes a couple times and I don't ever recall ending up with it in the final design, so it must not have added all that much value. On the negative side, it halves the capacitance. One technique to improve the phase noise in wide-band VCO's was shown by Ulrich Rhode. He uses several diodes in parallel in order to decrease the RF current in each diode, reportedly lowering losses and improving noise. I never tried it myself.

Joe

209. AM mobile

Newsgroup: rec.radio.amateur.homebrew

Anyone remember a three tube AM mobile rig for 80 meters? It used a 6146 modulator, a 6146 final, and I think a 12AQ6 oscillator. I built one and it worked great. I would like to find the schematic for that little rig.

I have a Sanyo laying here, apart, and it does. I am trying to find
the lens control circuits so I can mount a small CCD camera to it, and
use it to magnify what I am working on. The CRT has a seven pin base,
and a second anode connector on the side of the bell.

Your CRT would need four more terminals for electrostatic deflection,
and four output transistors to drive it. Since the tubes are small, and
run at fixed sweep frequencies, using magnetic deflection makes more
sense.

211. Superheterodyne mixer question

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-09 04:52:30 UTC
From: joeryahoocom@yahoo.com
Message-ID: <e08922c6.0401082052.252319be@posting.google.com>
Source record: 29598

I'm trying to settle a debate with a friend, and my knowledge of
mixers is pretty rusty.

Say you have a receiver whose IF is 455 kHz, and it's tuned to a
station at 1500 kHz. If all's working OK, at the output of the mixer
you should have four frequencies:

1500 (original signal)
1955 (oscillator signal - osc. working above the signal freq.)
3455 (sum)
455 (difference)

My question is by what process does the mixer produce the 3455 and 455
frequencies. I say it's an add and subtract process, my friend says
(via mathematics) it's a multiplication process. Who's right?

thanks,

Joe W9TXU

Was that the one in the 1965 ARRL Radio Amateur's Handbook?

If so, I have it and can post it on ABSE.

I built it in the late 50s, like 58 or 59. From QST I think. It may have
been in a later handbook. I just don't know.

Message-ID: <vvsu2hdu02ooe9@corp.supernews.com>
Source record: 29601

Your friend is right.

If you simply add or subtract two waveforms, no new frequencies are created. You end up with only the frequencies you started with and no more. (Theoretically, you could make one or more disappear if one of the added waveforms contained a precise negative of one or more frequency components of the other -- but you can never get any new frequencies.) That's because addition is a linear process, with linear having a precise definition that's appeared here a number of times before. (Subtraction is just addition, with one waveform inverted before adding.) Multiplication, though, is a nonlinear process by the precise definition used in circuit analysis, and it does create additional frequencies. Multiplying the two original signals of 1500 and 1955 generates the two new frequencies of 455 and 3455, for a total of four frequencies after multiplication. Adding them wouldn't do it.

Most good mixers are actually more like switches than multipliers, but they're still nonlinear -- very much so -- and don't do anything remotely like adding the two signals. A doubly balanced mixer produces the sum and difference frequencies while not letting the original two frequencies get through to the output.

The generation of the new frequencies by multiplication of the two originals is easily shown mathematically, as your friend says, with a short derivation by means of a trig identity. I'll be glad to post the derivation if you or other readers are interested, although it's widely available elsewhere.

Yes, your friend is right, but there is a grain of truth in what you are saying also.

A mixer multiplies two signals as your friend says and as said in the posting by W7EL. Signals can be represented by cosines, and the product of two cosines is:

cosA * cosB = 0.5(cos(A-B) - cos(A+B))

See product identities on http://www.swt.edu/slac/math/trigrev/trigrev.html and let A=2*pi*f1 and B=2*pi*f2.

So while the operation of the mixer is that signals are _multiplied_, the frequencies will _add_ or subtract.

Part of the confusion is that audio engineers talk about "mixing" where
they actually mean adding. Mixing - as RF engineers use the term - is
precisely what they don't want!

Mixers are amplitude modulators.
One signal modulates the amplitude of the other.
Trigonometrically we have -

2*Sin(A)*Sin(B) = Cos(A-B) - Cos(A+B)

Where the A-B and A+B terms are appropriately described as "the products".

In practice there are a great number of unwanted products output from a
mixer because many harmonics of A and B are generated in the process and all
continue to inter-modulate each other.

The wanted product, the IF, is usually A-B or A+B.

Well, ear is also somewhat non linear. So they are also doing mixing.

Fred.

Fred,
You're exactly correct! That's why a piano tuner person can strike a tuning fork and a piano key at the same time and hear the frequency difference as a low beat note.

As to Ian's comment...I don't think "adding" is the correct term either. "Multiplying" or "sampling" are more precise terms. A perfect balanced unity-gain mixer actually uses one of the input signals to sample the other. On the positive half cycle of the LO, one phase of the RF signal is sampled, and on the other half cycle of the LO the opposite phase of the RF is sampled. Mathematically, this is equivalent to multiplying the RF signal by +1 or -1 on alternating half cycles of the LO.

Sure. Just try to suppress ear non linear effects and see how miserable composers will feel without it and how poor the music will sound to our "marvellous new ears".

Or, convolving, if the frequency domain, which tells all the story.

Fred.

>Well, ear is also somewhat non linear. So they are also doing mixing.

What the audio engineers do at the "mixing desk" involves only adding.
What our ears do, is something else.

But in fact, our ears are very close to linear. There is a belief that
because we can hear "beat" frequencies, there must be some non-linear
mixing in our ears... but that is actually a fallacy. The way we hear
beat frequencies - the difference frequency between two separate audio
tones - is due to simple linear addition and subtraction of two sound
pressure waves. Non-linear mixing is not required.

(If non-linear mixing were involved, we'd hear the sum frequency as well
as the difference frequency... but in fact we don't, unless there is
some other source of non-linearity outside of our ears.)

Hearing beats does not require non-linear or multiplicative mixing -
please see my separate reply to Fred.

>As to Ian's comment...I don't think "adding" is the correct term either.

I was referring to what *audio* engineers call "mixing", which is
nothing else but simple adding or linear combining.

I agree with everything you say below...

>"Multiplying" or "sampling" are more precise terms. A perfect balanced
>unity-gain mixer actually uses one of the input signals to sample the other.
>On the positive half cycle of the LO, one phase of the RF signal is sampled,
>and on the other half cycle of the LO the opposite phase of the RF is
>sampled. Mathematically, this is equivalent to multiplying the RF signal by
>+1 or -1 on alternating half cycles of the LO.

...but the processes you describe are not what a straightforward audio
"mixing" desk does.

The device you describe above, an audio engineer would know as a
"modulator" or a "ring modulator". For example, the LO could be at a low
frequency, to get some kind of throbbing effect. Both RF and audio
engineers would agree, that is true modulation.

The difference is that RF engineers would also call that process
"mixing"... but audio engineers would not because, to in their
professional world, "mixing" means adding or linear combining.

If you already have a receiver that covers HF build a converter. QST has published plans for tx/rx transverters in the last 10 years or so, but (a) they're transverters so they're more complicated than you need and (b) they're for things like 12m to 20m. None the less there'll be interesting info there. You may also want to look in the current Handbook.

For casual listening you should be able to do it with an NE602/NE612, a 24MHz crystal and the appropriate input/output filters. The `602 has it's own oscillator so with the right battery power you could get by with no other active componants, even.

Disclaimer (disflamer?): Everything that Roy says is true enough to get you down the road of radio circuit design -- but:

To be absolutely, mathematically correct, if you hold your mouth right, a "perfect" mixer with it's driving oscillator, is a linear device. It is _not_ a time-invariant device. It's linear because the IF signal that results from putting in the sum of any two RF signals is exactly equal to the sum of the IF signals that each result from each of the RF signals. If it were nonlinear then this would not be the case (and it wouldn't be a useful device for mixing).

What gives a mixer it's "mixerness" is that it is linear but time-varying (output = input * some function of time). It is very easy to confuse time-varying linear with non-linear, and even easier in practice because in order to get the effect you need to use componant non-linearities to get the job done, just as you do with a class A amplifier. But it's usually harder to get the nonlinearities out of a mixer than an amplifier, so in real design you have to pay attention to non-linear effects like blocking and intermodulation in a mixer to a much greater extent than you do with an amplifier, and this reinforces the idea that a mixer is fundamentally nonlinear.

This means that when you're analyzing a mixer (and ignoring real-mixer things like intermodulation) you can still use all the linear circuit theory stuff as long as you stay away from anything that depends on time-invariance. This means that _simple_ Laplace and Fourier analysis is out, but you can still use _careful_ Fourier analysis to figure out what the output will be for a given input and oscillator frequency. In fact, that's exactly what you are doing when you analyze a mixer: all of the desired behavior of a mixer can be exactly predicted with Fourier analysis.

Bill,

You said:
" Any good technician will tell you it's an add and subtract process.
Any good engineer will bore you to tears with complicated mathematical
analysis.
Guess which answer is more useful for your purpose?"

Well of course...if you're only interested in what some of what comes out, then it's an 'add and subtract process'. But isn't that our initial definition of what we want a mixer to do? This is circular logic. You're chasing your own tail.

The original question was more in the vein of 'by what mechanism does a mixer produce sum and difference frequency components'. The correct answer is that it implements the mathematical product of the two input signals, and that product contains sum and difference frequencies in addition to a host of other frequencies that includes the original frequencies, all their harmonics, and every conceivable product of those frequencies and their harmonics. It's not just a simple 'add and subtract'. It just so happens that we're most interested in the sum and difference, but there is much, much more going on.

The "answer that is most useful for the purpose" is not necessarily the most simplistic. Consider the following profound statement from W.E. Deming:
"If you can't describe what you are doing as a process, then you don't know what you are doing"

Joe W3JDR

You're absolutely correct. Production of new frequency components can be done with either nonlinear or time-variant circuits. A square-law diode detector is an example of the first; a multiplier is an example of the second. I stand corrected -- thanks for pointing it out.

229. Heat sinks/variable transformers/misc offered

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-09 22:31:12 UTC
From: Roy Brock <roybro@sccoast.net>
Message-ID: <btnaf2$atth$1@news3.infoave.net>
Source record: 29616

Hello all,

I have a bunch of heatsinks I'd like to sell. Most are perfect for mobile power amps.
Some have enclosures where the face of the heatsink forms one side (the top) of the enclosure, and wings for mounting on the opposite side (again, perfect for mobile PAs). Enclosures/heatsinks just described are approximately 5.5" x 7.5". I have ten of them.
I have other heatsinks perfect for PAs that are 6.75" x 9.25"; I have four of these.
I have a couple that are a little larger than above, approx. 7.5" x 10.5". One has a single transistor PA on it already; stripline matching, so has to be 2M or upwards.
I also have some LARGE stuff for high current diodes/SCRs (>200 Amp) - mega surface area.
There are also various lengths of raised mount TO-3 style sink.
Lastly (heatsinks), I have a box of smaller (one TO-3) type sinks I will sell as a lot.

I also would like to sell five 2.25A 120-volt variable transformers, superior electric powerstat type 10C.

I have a single broadcast-pull 4-400 w/socket (its twin was broken in my absence under mysterious circumstances; I never used them) and a plate tuning cap, don't know the value, transmitting, ceramic ends, 27 plates total, 1/8" spacing. Surely someone out there could use them.

Make offer for anything you're interested in. If you want pics, just ask and I'll email 'em.

Thanks...Roy Brock

A lot of good stuff here and unfortunately some digression.

It might help here if you think this way. The basic RF or as you say, superhetrodyne mixer, does what it does by instantaneous voltages multiplication of the _instantaneous voltages_ of the two signals. There are many types of these RF mixers, but the one which is modeled with this concept will only give you the two frequencies as Roy's trig identity shows. You can take a spreadsheet and put a sine wave of one freq in one column and another freq in another column (use a pretty small angle step, say 1 degree or less - be careful the degree/radian issue doesn't mess you up) then make a formula in a third column which is A*B. You will see that the resulting "product" column has variations which are not the two input frequencies. It may not me real clear, but if it wiggles faster or slower that the originals, then it is a different frequency. (now I gotta do this so I see what it looks like for my self). However, better yet.....
The neatest example of this is to put the exact same frequency in both inputs columns! Then the "wiggles" of the sine wave will be very obvious. There will be no doubt about what is coming out of the multiplication. God, I love spreadsheets. (sorry here, the beginning of a sentence is capitalized).

Why does this Mister Wizzard stunt work? Because a circuit is doing something to the voltages present at any given time, and in this case it is a product thing.

SO, YES you do get the "Sum" and "Difference" frequencies out, so if you want to call that addition / subtraction while working "in the frequency domain" that's ok with me. However, all this other garbage holds, just the same.

If you make a circuit which gives as its output the product of the two input voltages, Roy's formula holds and you get the sum and difference frequencies only. This is what we commonly call a "balanced mixer". The term "balanced" comes from the concept that in this type, if you get the circuit set up or "balanced" just right, the two input signals don't appear at the output and the trig identity holds. I suppose it can be called the ideal type.

When you get into what is commonly called "modulation", you still have this type of instantaneous voltage multiplication, but usually, like in a Plate modulated Tube transmitter, it is not so perfect and some of the original input signals get through to the output (though the audio can't make it out to the antenna) and you get carrier (one of the input signals) as well. (I'm not going to get into the 'does the carrier vary in amplitude' or sideband arguments here.)

All this talk about many more than the two frequencies is the result of what we call "higher order" non linearities. This is just a way to describe distortion that keeps the original sine waves from being perfect sine waves in a circuit.

Also, the sampling talk will just confuse this basic issue, so I advise ignoring it for now.

FWIW: the model in my brain can somewhat consider time variant the same as non linearity since you get out something which ain't a simple scaled version of the input...

> never tried it myself.

If the diodes are the limiting factor, it can help.
The second diode seemed to do the most good,
the third, a little more, but any more didn't help
(in my designs).

The way the varactor is made will affect the
noise performance. Ask the manufacturers
which process yields their best phase-noise
performance. Most of them are very helpful.
As I recall, planar, epitaxial construction,
with thermal compression bonded leads
gave my best results. Hyperabrupt diodes
gave the worst. But things change rapidly
these days, so ask.

[snip]

Mixer, modulator, multiplier, demodulator, detector, switcher, balanced modulator, adder, subtractor, heh, heh....

The term mixer is overused, or... "overloaded" as the computer scientists like to say.

Yes indeed, too bad for beginners, but it's part of the mystique of our trade as well, that there are plenty of examples of misuse, misappropriation, and the outright abuse of terms and their meanings in our trade! Keeps gurus in business and nosey outsiders out, as well. :-) Heh, heh...

Even within the English speaking community, there is often no consistency of terminology use, for example "tube" versus "valve", etc...

British and American use of the term "mixer" in the television production equipment business has further confusing examples of overuse and overlapping meanings. In television production technology the term "mixer" is also used to describe switching and sepcial effects equipment and the terms are applied differently on each side of the Atlantic. What you Brits call a television "mixer" is called a television "switcher" in America, and what's more... the same names are used for the operators of the said mixing/switching equipment. [Grass Valley, Ross, Central Dynamics, etc... are manufacturers of such.] You can often see the equipment operator's names listed opposite the titles Mixer or Switcher on the TV screen when they roll the credits at the end of television shows. And to make things worse, the "function" of an audio "mixer" is again entirely different than a video "mixer", whilst television video mixers often contain integrated audio mixers. Impossible for beginners to figure out what experts are talking about, go figure!

Or is it simply that when using multiple varactors in parallel, the
amount of capacitance needed from each varactor is reduced, hence a
higher tuning voltage must be used with the same inductance ? With a
high tuning voltage, the capacitance/voltage ratio is smaller, hence
the capacitance difference would be smaller on the separate RF half
cycles. This would reduce the phase noise.

>If the diodes are the limiting factor, it can help.
>The second diode seemed to do the most good,
>the third, a little more, but any more didn't help

Your observations would support my theory, since adding further
varactors would only increase the tuning voltage slightly with the
same inductance.

The math does show otherwise.

When we talk about "square-law" and "third-order", we're actually buying into a whole package deal of math-based concepts. Logically, the deal is that we can't use those words *meaningfully* unless we also accept what the math tells us, namely:

1. Each order of distortion is independent of all the other orders. It generates its own individual package of output frequencies.

2. Frequencies that are in the same-order package *must* all be generated together (you can't have one of them without having all the others too).

3. Frequencies that are in different-order packages are totally separate and unconnected.

2f1 and 2f2 are part of the package of 2nd-order products, along with (f1 + f1) and (f1 - f2)... there are four 2nd-order output frequencies, no more and no less.

3f1, 3f2, (2f1 + f2), (2f1 - f2), (f1 + 2f1) and (f2 - 2f1) are all part of the 3rd-order package... there are six 3rd-order output frequencies, no more and no less.

A perfect square-law mixer produces only 2nd-order products. 2f1 and 2f2 are present at the output, but they do not "go round again" and mix with the input signals to produce (2f1 + f2) etc. Those 3rd-order products arise *entirely and exclusively* from 3rd-order distortion.

That conclusion follows by strict, non-negotiable mathematical logic from the fundamental definition of what "order of distortion" means.

As others have said, from the practical engineering point of view, the way you envision mixing products being produced is "purely academic".

But that "purely academic" debate is exactly what we're involved in
here... so here, it makes all the difference in the world.

Many early systems used separate cameras and a suitcase
VCR. My RCA camera had a removable viewfinder which
used a minature CRT with a yoke.

That would get you started, but you would need to change the front end coils
in order to make that work. There wouldn't be enough tuning range with the
current front end components. You might be able to change the padding caps,
but still........

Pete

There was an article about doing this in 73 about twenty years ago,
when conversions of PLL CB sets were alll the rage. It counted on
the injection frequency being on the high side, so the image frequency
was in the six meter band. I can't remember whether it worked out
directly, or if one had to fiddle with something.

Pete's right, the front end would have to be adjusted.

It's an interesting scheme, but oddly while it would require less
construction, it may be more daunting for a beginner to do such
modifications than for that beginner to build a converter as someone
suggested. You don't have to worry about tracking down a schematic
for the CB set, you don't have to worry about finding what's where (or
figure out what needs to be done when likely there aren't specific
instructions for the set in hand), and don't have to worry about working
in the confined spaces. Building a converter from scratch means you
can wait till you have a full schematic for parts that you can get,
and you can construct it in a fashion where there is plenty of space,
though of course it would need to be built in a small area for proper
performance.

>My question is by what process does the mixer produce the 3455 and 455
>frequencies. I say it's an add and subtract process, my friend says
>(via mathematics) it's a multiplication process. Who's right?

Neither and both! :-)

It depends on the definitions of "linearity," "mixing," and "adding."

In a perfect linear circuit, two or more signals can exist as separate
entities, none affecting any other. You can "mix" them (inject them)
with the group of signals. Since the circuit is perfectly linear, no new
frequencies are added which are attributed to a sum or difference of
existing frequency signal components.

In sound recording "mixing" and "adding" always refers to operation
with nearly-perfect linear circuits to a recording medium.

"Mixers" in radios are highly non-linear. Some are outright switches
(Tayloe Mixer), some are very nearly on-off switches (diode rings),
and some use gross distortion of normally-linear characteristics
(tubes, particularly pentagrids...and Gilbert Cell double-differential
transistor structures). NON-LINEARITY creates new frequencies.

Mixing (in a mixer circuit) an incoming signal with a local oscillator
creates a mathematical sum and difference of the signal and the
LO frequencies...in addition to the existing signal and LO
frequencies passing through the mixer circuit (balanced mixers will
suppress the LO and double-balanced mixers can suppress the
signal frequency as well).

In this process of mixer circuit mixing, the new frequency products
(using "products" in a very general sense, not just multiplication)

still retain the amplitudes of the original. The signal's amplitude containing AM sidebands is repeated at the new sum and difference frequencies. Relative phase is also preserved. If the signal has modulation components due to FM or PM, those appear on the new sum and difference frequencies. If the much-stronger LO contains any AM, FM, or PM, that is repeated on the new sum and difference frequency components as AM, FM, or PM.

It gets worse. :-) The LO is seldom a pure sinewave so it has harmonic content. New sum and difference frequencies will exist as a result of LO harmonics! [most of those are simply filtered out, dissipated, rejected] Scoping an LO injection waveform on a wideband oscilloscope might come as a shock... :-)

The "process" is all due to NON-LINEARITY. The mixer output contains the original signals plus components at frequencies which are the sum and difference of the original...plus a few more.

Mathematics is used as a way of explaining the non-linear mixing process. That isn't the full explaination but it is close enough. Don't get caught up in plus and minus signs on equations and too much argument over that...nor of the mathematical purists who play games with term re-arrangements and "hidden meanings."

Non-linearity of all amplifiers will cause heterodyne creations. A low-level example is the intermodulation distortion values such as "IP3.".

>One technique to improve the phase noise in wide-band VCO's was shown by
>Ulrich Rhode. He uses several diodes in parallel in order to decrease the RF
>current in each diode, reportedly lowering losses and improving noise. I
>never tried it myself.

Variable-capacitance diodes exhibit that phenomenon only in
reverse-DC-bias connections. In forward-DC-bias connection they
behave generally like ordinary diodes, conducting very little current
until about 0.6 V across the junction.

A single variable-capacitance diode across an RF circuit will conduct
- and thus have an effect on the RF tuned circuit - when the
combination of DC tuning bias and RF voltages are above the
forward-conduction breakpoint.

The purpose of "back-to-back" connection is to keep the (now two)
variable-capacitance diodes always in reverse-conduction...the RF
voltage (peak-to-peak) is not supposed to exceed either the break-
down voltage of the diodes or cause either of them to be forward-
biased during any part of the RF cycle.

With no forward conduction, the variable capacitance diodes remain
just that - variable capacitances.

When forward conduction occurs, it adds more non-linearity to the
RF circuit and tends to decrease the action of the variable capacitance.

When used in low-level RF stages of a receiver input, the RF voltage
hardly ever exceeds 1 V peak-to-peak and thus the variable
capacitance diode never goes into forward conduction. Single diodes
can be used there without doubling-up.

Getting a spellchecker going on your system might be a good start.
;-)

You may find it a bit of a challenge to get hold of CA3046's. It
appears (from a Google search) that they're now made by Intersil

FWIW, that IC is nothing more than an NPN transistor array. You
may be able to sub discrete components.

Nope. They both have their strenghts and weaknesses in different
applications.
Certainly I'd say FETs are easier to understand in terms of how they
work; being more 'valve-like' than the BJT. But that's about it.

Frank (motg@stratos.net) writes:
> Anyone have any thoughts on this? Just a general question. Why or why not

But what makes you ask the question?

When the transistor came along, almost right away they started to
be used in equipment. This despite the fact that those early bipolar
transistors were not all that suitable for some of the applications.
The FET came along in the early sixties, and it was seen as the salvation,
as the way of the future. But to some extent it was an illusion. The FET
was good for some things, and did have better strong signal handling
ability than the bipolars of the day. But, the bipolar and applying
it just hadn't moved far enough along the curve. By 1971, the ham magazines
(and obviously the professional literature) was talking in terms of
strong signal bipolars, using power transistors and biasing them
almost as if they were being used in transmitters despite the application
being for receive. And of course, better bipolars were coming along,
that gave good performance at the higher frequencies.

Somewhere in there, the schottky diode started appearing in practical
circuits, and obviously it made for a good mixer

The MOSFET came along, late sixties or early seventies, and it was seen
as an extension of the FET, in that they were both high input impedance
devices, and were seen as the future. They were seen as the future,
but that was thirty years ago.

Nowadays, MOSFETs for RF are relatively uncommon. You can do what
you need with bipolar transistors, or in the case of mixers (which
was seen as a prime use for dual-gate MOSFETs), passive diode mixers
are seen as the way to go.

If you'd asked this question thirty or even twenty years ago, it would
seem like an opportune question. MOSFETs were still relatively new,
and they seemed like a solution. But their use in RF circuits peaked
more or less. So thirty years later, the question doesn't seem to
be one to ask, since enough time has gone by that we know they will
not take over from bipolar transistors.

That would be news to manufacturers of broadcast transmitters.

I think that you'll find that the usual solid state AM transmitter is a huge D-to-A converter consisting of lots of MOSFETS. The 50-kW Harris DX-50 uses that technique and is just about the "standard" 50-kW rig. It is used by many stations. The transistors are in modules that can be hot-swapped while the rig is on the air. Distortion is within limits even with a few of the modules missing.

MOSFETs are also used as the output amplifiers in high power FM broadcast 100-MHz transmitters - certainly up to the 10-kW level.

Besides the reasons already given for RF, in power electronics, the Ron of a BJT is far lower than a MOSFET. There is a melding of the two technologies, called the IGBT (Insulated Gate Bipolar Transistor), but they are only good up to a few dozens of KHz where true power bipolars can switch ealily into the tens of MHz.

For audio and instrument applications where noise levels need to be below 2nV/Hz, MOSFETS can't even go there (without being dunked in cryogenic fluid).

> knowledge in electronics.

Since it's purely for receiving, I assume you don't have a license for it, and are interested in the hobby in more depth than just hearing a bunch of old men talk about the XYLs ;-)

Probably the cheapest way to /build/ one would be to scour the internet for any kind of receiver schematic... I saw some not too long ago - I'll make a note here to try browsing for it again (but it will have to be about a week from now as tomorrow I'll spend most of my time doing work for my dad and homework for college, then next week it's alllll school). I MIGHT get a chance to do some stuff Tuesday, dunno...

Anyway, it's real simple, if you don't care too much about knowing exactly what frequency you're listening to. You find a receiver schematic on the net (I'll try to find one for you if you want), then instead of using the coils described, you experiment with your own - larger diameter, longer length, closer turns, further spread apart, center tapped, etc.

You'll need a variable capacitor. Probably best to go to the Dollar General and pick up one of those cheapie $5 rotary tunable (the kind that use a knob) handheld AM/FM receivers. Then, just steal the variable cap out of it. It will have six leads on it, for 4 possible pairs (the two middle leads are tied together (common). There will be a 20-40 pf pair, and a 20-120 pf pair. The 20-120 will give better frequency spread, but very coarse tuning and maybe a touch of selectivity loss. Still, with the right coils, the 20-40 pf pair should do nicely.

In fact, now that I think about it, you might be able to make do with just one of those by changing the coils (there are usually only 2 or 3 of them).

Wow, a $5 portable 6m receiver that can also pick up low VHF TV channels - excellent!

FWIW, I've built an FM Broadcast band transmitter... only 18 parts, not counting breadboard/wire/antenna/input/LED parts, and I get 1/8 mile range on it. Anywhoo, I have been able to interfere with my TV (only a few feet away) by using different coils and capacitor leads, so it should be fairly easy to get what you want for cheap if you're patient and don't mind fiddling with coils and such. Of course, it's not going to receive beautifully, nor very selectively, but it should be able to pick up ppl in your area.

Let me know if you want help finding a simple schematic - and I'm talking
just like 20 parts or so that you can pick up at the radio smack.

I know how that can be.....parts for older units are hard to
get ahold of. I remember years ago, I called Rockwell for a quote on the
main tuning knob for a 651S-1. The price for tooling, etc was 5000 dollars!
That receiver is no longer supported, and the only way to get ahold of parts
for that unit is from the surplus market.
Same thing goes for the KWM380/HF380.

262. Overvoltage and reverse voltage protection

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-11 11:44:19 UTC
From: Richard Hosking <zaprichardh@iinet.net.au>
Message-ID: <40013713.30203@iinet.net.au>
Source record: 29549

Dear all
I want to design a power supply for a low power rig with protection for reverse and overvoltage. The requirement would be about 1A at 12-14V. What is the best way of achieving this? I guess a diode would give reverse voltage protection but the 0.6V drop is a problem.

Richard

263. SMPS and noise

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-11 11:52:46 UTC
From: Richard Hosking <zaprichardh@iinet.net.au>
Message-ID: <4001390E.9050505@iinet.net.au>
Source record: 29550

Dear all
I want to design a power supply for a low power portable HF SSB rig with maximum efficiency from a 12V battery
I will need +1.8V at around 200mA, +5V at low current, and +/-12V, with the +12V at 1A unregulated. I thought of using a MAX1865 SMPS chip which has multiple outputs with good efficiency. However I am conscious that in a quiet analogue environment, the SMPS may be a problem with switching noise. Is this a feasible idea? Should I use several separate chips? What precautions should be taken? (I have read the Maxim app notes on PCB layout and noise reduction, but I am not sure whether this will be sufficient in this environment)

Thanks

Richard

They can not make any money if they do not sell ney radios. Most companies make and support items for a short period of time. After that they have the next modle ready to go. By pricing the repairs at a very high price many will buy the new stuff. It is difficult to keep up with all the parts of equipment that is years old.

I forgot the price but in the news paper about 10 years ago it cost the military about $ 20 K just to get a diode that should have cost a couple of dollars. The military was out of them and the manufacture had to make a run of a few thousand . You just can not make one simiconductor.

Rick,
one way for reverse protection is to include a bridge recifier in the
rigs power line (internally fitted), but this causes a drop in
available volts.

I prefer a diode into a relay coil, with the relay contacts enabling
the power when the relay coil is correctly polarised and powered (
also internally fitted).

This enables full volts to the rig and also gives reverse protection,
however this is at the cost of further (and some may say excessive)
drain of the power source.
Over voltage should be by fuse and a crowbar circuit. Do a search on
crowbar for details.

The diode + relay circuit should be obvious to you, I use a 9v relay
coil with a 1N4001 in the activation side and a DPDT contact,in
parallel, to switch the power. For the power you are talking about a
14pin DIL relay should be adequate.

Mitar

I found some time this morning and decided to go ahead and search for some radios... I don't know what your requirements are, in total, nor do I know what search engine you use, but I used google and found this results page:

http://www.google.com/search?q=schematic+fm+radio+receiver

Of particular interest to me personally was found on the first page, about the sixth result:

http://www.commlinx.com.au/rf.htm

There are many others in the results, and yes, you'll have to sift through some other very distracting (read: Interesting) stuff to find the receivers, but they're there.

HIH, and good luck

If you already have a fuse & crowbar circuit for overvoltage, wouldn't the easy way to handle reverse polarity be a diode hooked in the (normally) non-conducting direction across the output?

Hi Rob,

KT315 is npn, KT361 in pnp. Both are 150mW, about 25V, 50mA, low frequency.
Seen from the marking, leads down, left to right: ECB. I guess any Si BJT
would be able to replace them.
You need any other info?

They already had the bare dies, and the mounts. These receivers were barely four years old and had cost close to $5,000 each we had about 100 of them in service. They had a high failure rate and had used up all their spares and wanted us to pay more than the price of a new unit per transistor, so I fixed the units I could, and replaced the others with new Microdyne equipment. It wasn't very long before no one would buy their commercial SAT TV equipment because of poor support. By the time they were out of their hand mounted dies they could have bought a comparable part already assembled for repairs. I worked in that business a few years ago, and the company supported most equipment for 15 years. When they dropped their commercial SAT TV product line, they sold the remaining parts and all rights to one of their techs, and he still supports them from his one man shop.

There is a good chance that while they were looking for that part, another military installation was pitching it into the scrap bin to be auctioned off for salvage. Today there are companies that specialize in producing short runs of obsolete semiconductors, and others that buy up small stocks of every part they find on the spot market to provide EOL support.

Lansdale is one company that is licensed by Motorola / ON Semi to to manufacture most of their discontinued products.

http://shop.store.yahoo.com/americanmicrosemiconductor/index.html is
a company with a lot of oddball semis for EOL support.

I'm not understanding something here. You want to design a power supply that protects against reverse voltage and overvoltage. OK. Is this power supply a battery or are you actually building a power supply that runs from the wall outlet?

The requirements are quite different, depending on what you are trying to achieve.

Jim

Richard Hosking <zaprichardh@iinet.net.au>

Power Schottky diodes are available that have a forward voltage
drop of 0.3 or less. More expensive, yes, but they really do work.

It is not just a question about MAKING, the army must use MIL-SPEC
devices, and how do they go on making such.... They probably cannot
use an ordinary device for any reason - even in non-critical
applications. Take 2N525 , it is MIL-spec'ed, but most of them are
probably defective today and it has been much better devices to find
for the last 40 years

In British Telecom we had to use CV-numbered semiconductors, although
we could use normal types in the IMTR labs, but it should be
equivalent for a CV-numbered device, the only one I remember now - 25
years later is CV7127. Fortunately not so stupid in Norwegian Telecom

The worst is suppression of 150MHz, it is almost impossible to
suppress it. Bought some UK commercial integrated modules for 432MHz
which was fed from 144MHz 1W, had a 20W amplifier within a very well
screened and silvered box, but radiation on 144MHz were almost
impossible to suppress, the only way out was to place it deep at the
lowest point of the basement with ferrite chokes on the cables

It was a series of articles in an English magazine about conversions,
and believe I've seen a book mentioned at RSGB bookshop

Another idea is to use the 27MHz exciter and receiver as original
instead of converting it, OZ7IS Ivan used a 27MHz transceiver with
70cm transverter for a simple solution in his car

switching noise. Is this a feasible idea? >>

Richard-

This will probably be a good learning experience for you.

I purchased the Radio Shack switch-mode power supply, and was not surprised when it caused severe interference with my receiver. Then I bought an MFJ 25 ampere supply that had a good reputation, but it also caused i some interference.

When I bought a new Icom rig, it came with their switching supply. Although it is the quietest of the three, there is also an increase in the noise floor when it is in use.

To be fair, I must mention that I'm using a magnet-mount antenna on a nearby clothes dryer. An outdoor antenna would certainly receive less radiation from the power supply. At least you see how easy it is to pick up the switching noise, and how hard it may be to eliminate it!

It was obviously hand-built, so it's probably not from a kit. You'd have a better chance of IDing it if you posted the list of IC's -- that may ring a bell for someone.

Better yet, since all the IC's are socketed and since reversing the power supply probably damaged any that aren't destroyed completely, why not replace them wholesale?

Or keep the nicely made mechanical work in the cabinet and put in brand new keyer guts? This may be the least expensive of all.

With the perf board wiring -- sure looks like a homebrew project -- not a
kit.

Wiring and panel IDs appear nicely done.

A lot of these homebrew projects used a Curtis keyer chip 8044ABM -- see
URL:
http://www.arrl.org/news/features/2002/02/04/2/?nc=1

Good Luck

I'd like to call it "the PYE method" since it is generally applied in
those Westminster, Vanguard and Cambridge sets, while other
manufacturers only use a diode. I've copied it for the larger sets
which are often used in different places. The application of relay has
the advantage that nothing happens if you use the wrong polarity -
unless you have shortcircuit between two chassises, then you should
apply a two-pole relay.
Make sure that the relay stays operated under different operation,
check that the relay operates with 9V. Remember to put a diode or
other spark suppression across the coil, too.

Another trick I've seen is to use a hefty power MOSFET (one with a low
Rds[on]), with the source and drain leads reversed, in series with the
power. Depending on the voltages involved, you can either connect the
gate directly to the opposite side of the power supply, or (if the
supply voltage may exceed the Vgs limit) to a high-Z resistive divider.

When a power supply of the correct polarity is hooked up, the MOSFET's
intrinsic substrate diode is biased forward (conducting normally) and
the MOSFET is turned on "hard" (giving a low Rds, and thus a very low
forward voltage drop). If the supply is hooked up backwards, the
MOSFET is turned off (the gate is pulled down towards hard depletion)
and the substrate diode is reverse-biased, switching it off.

Not my idea originally, by any means. If I recall correctly I first
saw it in Bob Pease's "Troubleshooting Analog Circuits" book - a
text I recommend to anyone who is fiddling around with analog
circuitry in any way.

Jim
The rig will be powered from a 12V source eg battery/AC wallwart
/whatever. However, internally the rig needs various voltages, including
1.8V for logic and -12V. I want to ptotect against inadvertent
overvoltage or reverse voltage. I want it to be as efficient as
possible, so I dont want to use a linear regulator. SMPS seems the
obvious choice. I may well shield the PSU section, and isolate the
ground etc to reduce noise. I was seeking advice from the experts here
as to whether the idea is feasible and whether there is a redaymade
solution.

A more common explanation of the "nonsense at the end" is that it's a
"hashbuster" - a purely random string, different in each individual
copy of the posted or emailed spam. Its goal is to [attempt to]
defeat ISP-based spamfilters, which attempt to identify multi-posted
USENET articles and spam email by looking for identical subjects,
identical contents, etc.

Spammers of all sorts (amtisemitic and otherwise) have been doing this
for years. I believe that some of the better spam-detection software
is now capable of looking for these gibberish words/phrases, and
scoring the articles/email as "probably spam" due to their presence.

>indeed, if you could tell me about a MOSFET without protexion diode

That's why I mentioned hooking it up with the source and drain leads
in the reverse of the usual orientation.

In the normal hookup situation, the intrinsic/substrate/protection
diode would prevent the circuit from working as one would want (as you
clearly understand). However, by hooking up the MOSFET "backwards"
(e.g. an NMOSFET with the drain on the negative side), the orientation
of the intrinsic diode is reversed. It'll be forward-biased when the
power supply is hooked up the way you want it, and would be
conductive. It probably won't have a chance to conduct, though, since
you'll be biasing the gate up several volts above either the source or
drain pins, turning on the MOSFET, and the relatively low Rds[on] of
the MOSFET will keep the voltage drop across the MOSFET down below the
substrate diode's voltage drop.

If the supply connections are reversed, the MOSFET itself will be
biased off, and the intrinsic protection diode will be reverse-biased
and will not conduct.

It's an odd trick. Many (most?) JFETs have a highly symmetrical
internal construction - the distinction between source and drain is a
matter of convention rather than construction. A typical MOSFET's
construction is not entirely symmetrical... but, according to the
description I've read of this trick in Pease's book, it _is_
symmetrical enough to allow it to be used with source and drain
reversed, in this particular application. By flipping 'em around, you
make the intrinsic diode work for you rather than against you.

Source record: 29582

Ok, many of you have suggested rather than just simulation I should actually build something. Joe (W3JDR) has kindly donated a circuit diagram which I started off with.

Best way to get going quickly is dead bug style, soldered straight to the copper side of a PCB. I have never used this style of construction as it looked flimsy, but it looked like a good way to go just for prototyping. Well, the circuit went together fast and the finished product is very steady, so I am now a convert to this construction method! I may need a new iron though, as the basic low power model I have struggled to heat up the large area of board.

Firstly I built the circuit (almost) as directed, slight modifications were made to suit parts I had. Fixed capacitors were used as this allowed evaluation without worrying about the diodes performance. The oscillation voltage across the tank was about 1 vp-p measured with an older 50MHz CRO and a 1:1 probe. Oscillation seemed stable and I liked the result.

Question: I used the ARRL equation for a cylindrical inductor and seemed way off (50%). Should I expect the copper sheet to affect the inductance, and how.

I then replaced the fixed capacitors with BB909 (3-30pF) diodes. The result wasn't so good. Oscillation voltage was less (lower Q tank maybe) and the stablility seemed poor (again poor Q). I will attempt more measurements tonight.

James.

The difference between a mil-spec'd part and a commerical part is mainly
one of documentation. A series of tests are then specified for the
completed parts to make sure they meet their specifications. The care
imposed on the manufacturing process ensures that the parts are built
correctly. It says nothing about the robustness of the design though, it
just ensures that the design parameters are met.

Read Linear Tech www.linear.com 's Application Note 70 -- they have conquered noise by using slew-control switching techniques. Instead of the complete circuit used in the ARRL design you can jump off and use a slew control chip. The prices of the Linear slew control chips are not bad, probably $5 or $6 from Digikey. (and they can be purchased directly from Linear in quantities less than 500.)

The other thing I have pondered is using a regular gate driver and a 2nd order low pass filter to approximate a sine wave. You lose a lot of efficiency going from a square wave to one which is rounded off, and a filter has issues all its own issues, but I would think that "noise" or "hash" would drop tremendously.

Hi Dan,

Gee, Just when I thought I knew everything about a TS-440, I see/read
something new!!

What exactly is this cable, and what does it calibrate? If you can
tell me more I'll bet I can help you.

I have built a number of interfaces for the TS-440 that connect the
rig to a PC for all kinds of purposes.

Could this be a copy of the Heathkit keyer from the mid seventies ?

It's hard to see the name of the chips and my guess is TTL's.

Just a guess....

OK This is an all glass, flat-end envelope. Not much larger than a 50C5,
but a bit larger. Coated, can't see inside.
Yikes! they actually used magnetic deflection. I was hoping for
electrostatic, but with 9 pins that may be difficult. Been too long to
remember how many electrodes are needed for grid, focus & any more anodes.
Leseee.
2 fil
1-cathode.
4- dif plates
1-focus
1- accel anode

That's 9......maybe you need more...Oops, forgot the grid. Make the cathode
common with one of the filament lines or make it directly heated.......Oh
well. If it needs coils it'll make a nice conversation piece.

It's a simple wire that the owners manual on page 24 shows where to hook it
up. Instructions on usage are also there.

Nope. I think the Heathkit had a lot less parts

> It's hard to see the name of the chips and my guess is TTL's.

I blew up the picture and I *think* I saw 4401 and 4013. For a while there
CMOS parts were all the rage in keyers.

> > Or keep the nicely made mechanical work in the cabinet and put in brand
> > new
> > keyer guts? This may be the least expensive of all.

The mechanical work really is nice, isn't it. These days you can replace
the whole works with a TiCK or any of a hundred TiCK clones, or better yet,
stick in a PIC and roll your own logic so you get the feature set you want.

I think the bottom-end TiCK chip is around ten bucks. All it needs is a
power supply, which can be a watch battery, and a keying transistor, which
is probably already there ... maybe the supply, too. For a few more bucks
you can add all sorts of features, either through higher end TiCK's
(www.bright.net/~kanga/kanga) or Island Keyer (www.morsex.com), or the K1EL
keyer (www.k1el.com), or .. or ... or ...

..

I've recently started using the WinAVR toolkit, which
consists of GCC ported to the AVR family, a very
comprehensive avr-libc implementation, and all of
the associated Gnu-based build tools. It's really
quite snazzy and it's the price that hams love: free.

I did spend $80 for the Atmel STK500 programmer kit from
Digi-Key, but that's all I needed.

Overall, the AVR port of GCC seems excellent, really excellent.

Hi,

according to an old issue of UKW-Berichte the pinout is:

1: NC
2: IN
3: /IN
4: GND
5: Divide ratio (0V: divide ratio 256; +5V: divide ratio 64)
6: OUT
7: /OUT
8: +5V

Frequency range 70 MHz to 1300 MHz

I might also have a data sheet but it will take some time to find it.

I feel the AVR instruction set is superior to the PIC. It's a much easier instruction set to program for in assembly, and it is designed with C in mind. This means that the AVR will run the same thing faster, and with less code space. If it were an engineer asking I would recommend that the AVR be given precidence. If you must have BASIC, or if you must have some peripheral that's available on the PIC that's not available on the AVR, then that's the way you'll need to go.

Otherwise learn C and use an AVR.

It's a pretty standard layout, probably a cmos keyer that someone wired on an experimenters board using telephone wire. You can search through the arrl handbooks for information on earlier cmos keyers.

I've seen a few like it, HRO ("hugh rip off")(not really) which is is Ham Radio Outlet put out a pre-built one knob keyer back in the 80's that looks just like this circuit, less the mechanical keys. There were also projects like it in the handbook, based on revisions of the earlier wb4??? designs... which migrated into the Autek Accu Keyer layout.

It took me almost ten years to find one, but I did locate a replacement which included the circuit diagram. I could make it available on the http://sonic.ucdavis.edu server if you're interested.

The small board underneath is probably a 555 timer set up for sidetone. My old World Radio Labs Galaxy III (3) didn't have one, so we'd have to monitor our outbound cw by listening to the power supply hum.

cheers

I really wasn't trying to say "AVR is better than PIC", I was just
pointing out an alternative that's totally free (and open-source).

> Otherwise learn C and use an AVR.

But, I must say, I totally agree with you. I'm
quite pleased with the AVR-GCC port and avr-libc.
Sure, if you insist on using the full floating-point
printf, it's like 5k for "hello world", but even that's
not bad really.

Hello,

I'm sorry for crossposting, but I need fast infos if available.

I've the opportunity to acquire for a good price a not so young
Rohde&Schwartz spectrum analyzer :

Polarad 632C-1

Unfortunately, I can't find any infos about it, except I was told it's a
100KHz-1GHz one, and I've got pics of the front and rear panels. But still I
find these infos somewhat meager.

Of course I've googled, tried R&S site and... not avail.

Any info here, advice from who used one...

Thanks,

Fred.

Yes, that is what it seems to be; however, having purchased my TS-440 secondhand, the cable was not supplied, so I had no knowledge of its existence until reading the manual.

What made me think that it was more than a wire was the wording in the manual. It states that this cable has a one-pin-end and a two-pin-end. I did not know if this cable contained some simple circuit or what.

Thanks for the enlightenment.

315. The Pickett N-16 ES Slide Rule

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-13 03:49:49 UTC
From: jsavard@ecn.aSBLOKb.caNADA.invalid
Message-ID: <400368ef.321301@news.ecn.ab.ca>
Source record: 29510

In the year 2002, someone posted a message to this group noting that he had forgotten the use of the specialized electronic scales on the rear of his Pickett N-16 ES slide rule.

The thread encompassed a total of 30 posts in its life, but in none of the 29 other posts was his question answered, although many posts contained interesting reminisences of that fascinating mathematical instrument, the slide rule. (One or more of those posts, due to unfamiliarity with this particular slide rule, were written with the assumption he had forgotten to use the log-log scales or other standard slide rule scales, but in fact the use of those scales is obvious in comparison to the use of the electronic scales on the other side, and it seemed to me that these were the only ones with which he had a question.)

I was unsure of the proper way to decode the E-mail address in the message, or whether it was still valid. In hopes that the individual concerned is still an active participant in this newsgroup, I post here now, with an answer to his question.

At the web site

http://sliderule.ozmanor.com/man/man-download.html

there is not one, but rather there are two, versions of the manual provided for this slide rule.

And on my own web site, at

http://home.ecn.ab.ca/~jsavard/other/sr02.htm

among much other information related to slide rules, are the results of a study of the manuals for this slide rule, which yielded to me the meanings of the various scales thereon.

316. Legal limit from a FT-817?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-13 05:53:43 UTC
From: Ken Bessler <kg0wxIHATESPAM@yahoo.com>
Message-ID: <bu0152$66g60$1@ID-213023.news.uni-berlin.de>
Source record: 29502

Here is the project idea:

Exiter: Yaesu FT-817 set to 1w
Driver: EB63 amp kit from Communication Concepts
Driver filters: 160/80/40/20/15/10 meter filters from Comm Con.
Final amp: Ameritron AL-1500.....

The cost of the components for the driver is only $182.00 - I'd
have to add a case, bandswitch, etc.

I'm currently building the K5OOR hfpack amp but it will only
put out 35 watts which would not be enough to drive any of
the commercial amps on the market to legal limit, right?

Opinions?

Well.

Here in Canada, they got out of the small parts business years ago. HOWEVER,
the parts can still be bought on-line at RatShack (as they are known here). But
who wants to buy just one IC or transistor or resistor to finish that project on
line.
Now, would you believe, they are finally starting to stock a few small parts once
again ?
I needed two 1N34A diodes last week to repair an antenna tuner for a friend.
My stock was nil, so on the off chance, I called Radio Shack. Sure enough, they
are back on the shelves again, at 10 for about 4 bucks including the 15 % tax.
What I can't find locally is two small dial lamps to replace the ones in a Yaesu
FT-212RH. Radio shack has 12 volt bulbs, Yaesu used 9 volt bulbs. No hobby
type stores here stock anything other than 14 volt bulbs.

In Canada, it's very hard top get small quantities of small parts even when you
can find someone that has what you need. I needed 7 zener diodes to do a project
and had to buy a minimum order of 500. Good thing they were only 7 cents each.

321. Drake TR-3 transceiver synthesizer upgrade

Newsgroup: rec.radio.amateur.homebrew

Date: Sat, 10 Jan 2004 13:43:36 -0600
Subject: drake-mod

LOW BUDGET - HIGH PERFORMANCE
Upgrade for Older Bargain Transceivers.

One of the main reasons that older transceivers were abandoned was the need for strict frequency stability. Most amateurs communicating on SSB today have come to expect transceivers to maintain frequency stability to within 50 Hz of the desired frequency for natural voice intelligibility and uniformity
within a group.
Note: This project was apparently of no interest to one of the Ham magazines so I will submit it for this newsgroup. With such widespread exposure, perhaps a small percentage will find it of interest. It is rather lengthy because it provides some theory of the design so that it can be adapted for other similar equpment.

Several of the older vacuum tube models otherwise provided very good basic performance.....150 to 300 watts PEP with very good band-pass filters providing steep-skirted selectivity. Vacuum tubes normally last many years. At such bargain prices, and with modification, these transceivers can provide a good interim station for younger amateurs who have limited money, but plenty of experimental enthusiasm. Many older amateurs who already have modern transceivers sometimes enjoy working on side projects as a creative extension of the hobby.

The Drake-TR3 transceiver is described in this article. It is frequently available on E-bay, and at Hamfests for surprisingly low cost. It (and probably
Drake-TR4) seem ideal for this project: The same VFO range (4.9 to 5.5 MHz) is used on all bands, and is quite stable even before modification. It has two high quality sideband filters (USB&LSB), so that no frequencies have to be changed when switching sidebands. The second requirement is an old CB transceiver. It does not have to be working, except for features which are probably still useful: the internal 10.240 MHz crystal oscillator, the progammable divider-phase-locking synthesizer IC (such as a PLL02A, and several others) and the 5.4 volt regulator. Either a 23 or 40 channel, and AM or SSB models can be used. The 40 channel provides more channels if you choose the simpler limited option. Many channels provide suitable divisor numbers, while others will not without
modification.
The more interesting and more useful option however, is to use nine-positions of miniature switches to fully control the PLL

counter-lines
for the maximum divider numbers from 1 to 512.
Since several types of transceivers may be of interest, and a variety of junk box crystals from World War 2 are often available, more detail of the design
theory will be described.
The fundamental theory of the original CB is this: The internal 10.240 MHz crystal oscillator (10,240 kHz) is internally divided by 1024 in the PLL IC, which results in a 10 kHz reference. Then the VFO is mixed with a crystal oscillator to yield a difference frequency, in the 2 to 3 MHz range. This 2000 to 3000 kHz is divided by 200 to 300 (depending on which of the CB channels the selector switch is on) to yield 10 kHz. This is compared to the reference 10 kHz in the phase-detector and produces a DC control voltage out which changes direction according to whether the VFO is slightly high, or
slightly low in frequency. This is connected to a vari-cap diode in the VFO to force it to lock to the correct frequency. A note of interest at this point: To avoid confusion later when using the Truth Charts associated with the channel selector and the programming logic, there are five gaps in the CB frequency range where it advances 20 kHz instead of 10 kHz. Also channels 24 and 25 are inserted ahead (frequency-wise) between channel 22 and 23 per the EIA numbering plan. Knowing these exceptions will help avoid confusion when writing down a TRUTH-TABLE for your model, i.e. following the trend of binary numbers advancing by one for each channel number, except for those noted above.
Power for the CB and additional components can be conveniently supplied by half-wave rectifying the 12.6 AC filament supply in the Drake TR-3. This yields about +17 vdc unloaded with a large filter capacitor. A series dropping resistor of about 22 ohms (2W) was used to drop the voltage down to about 12 volts. It is probably wise to get the +12 volts for the the additional transistors from the load side of the CB power switch to avoid the +17.5 surge stored in the capacitor.

Getting to the design theory of this Drake TR-3 upgrade: The original CB 10.240 MHz crystal oscillator and its circuits to the PLL-02A synthesizer are left intact to provide the 10kHz reference. The requirement now is to take the output of the DrakeVFO (4.9 to 5.5 MHz) and divide it down to 10kHz. These frequencies are too high to divide down directly and are mixed with a separate crystal oscillator to translate them down to the 2 or 3 MHz range. The CB channel selector switch provides 40 divider values by switching binary lines HI or LOW. Fundamentally, the PLL02A is capable of division N=1 to 512, but only 40 divisions are customized for the original CB requirements and will be modified for use on the transceiver as perceived by utilizing the Truth Charts of binary logic. Usually the 64 bit (pin 9) is isolated from the channel switch and tied HI for more options on this model (Kraco KCB-4020).
Pins 7,8,9,10,11,12,13,14,15 (when +5.4v HI), respectively represent 256,128,64,32,16,8,4,2,1 divisors. The effective division is the sum of all the HI
pins. The 256 and 128 are often wired HI or LOW and the remainder are

switched by the channel selector.

The theory is best explained by taking the three cases used in the Drake TR-3. It uses an I.F. frequency of 9 MHz. On 80 M, an incoming frequency of 3875 kHz gets mixed with a VFO frequency required to provide an I.F. frequency of 9 MHz. Thus 9000 minus 3875 requires the VFO to be at 5125 kHz. This is too high to divide directly, so a rather arbitrary crystal frequency oscillator of 7425 kHz (a good choice because it allows coverage of the five older phone bands and has a last digit of 5). It is mixed with the Drake VFO which has a small coax appearing near an optional connector at the bottom cover. This yields a difference of 2300 kHz which is divisible by 10 and is sent to the PLL02A. It is programmed to divide by 230 yielding 10 kHz internally to be phase-compared to the internal reference 10 kHz. The phase detector provides a positive (but directional) DC out which connects to a vari-cap or varactor which changes its capacity according to the DC reverse-bias applied. In this project, an ordinary Power MosFet was used in a special configuration to provide better capacitance control. The TR-3 offers an exposed bare wire going from a tap on the VFO inductor, to pin 7 on V-2. A 47 Pf coupling capacitor is added from there to the MosFet device as seen in the schematic.

A second case on 20 Meters is an incoming frequency of 14.320 MHz which is higher than the I.F. and is mixed with the VFO to provide 9 Mhz.14,320 minus 9000 requires the VFO to be to be 5320 kHz. An alternate crystal in the vicinity of the first is used, but this time having a last digit of zero to assure that the mixer output is divisible by ten. 7370 kHz was used and 7370 minus 5320 yields 2050 kHz. The program pins are set to divide by 205 to yield the required 10 kHz. Note that alternating between these two crystals provides lock-in every 5 kHz. Any other favorite frequency could be accommodated with a different crystal with the appropriate last digit to provide division by 10. Substituting a good VXO circuit might be a substitute for changing crystals. It should be noted that a few PLL-02A's already include the option of grounding pin #4 which causes it to divide the 10.240 MHz xtal by 2048 and provides an internal reference of 5 kHz. In this case, either of the added crystal options above would provide lock every 5 kHz. If your PLL-02A does not have the 5 kHz option (the NTE-1167 does not), it can be done with one section of a SN74LS74 flip-flop by tying pins 1,4,14 to +5, tie pin 2 to 6, trigger IN on pin 3, 5120 kHz out from pin 5, and of course pin 7 is ground. A +5 voltage regulator supplied from +12 volts will provide power. The trigger input to CK, pin 3 may require an NPN 5 volt emitter follower with a 200 ohm emitter resistor to trigger the flip-flop.

The third cases of 40, 15, and 10 M all use the Drake mixer crystal appropriate for that band. It is mixed with the VFO and the difference frequency can be considered the "virtual" VFO. On 15 Meters Drake uses a 35.5 MHz crystal. For an incoming frequency of 21.300 MHz, 21,300 plus 9,000 requires a "virtual" VFO of 30,300. The 35,500 crystal minus actual VFO = "virtual" 30,300, or actual VFO=5200 kHz.
Select the 7370 kHz mixer crystal again, and 7370 minus 5200 yields 2170.

Dividing by 217 yields 10 kHz in the PLL.

It may be preferable for some to have more direct control of the programming pins on the PLL:
Physically separate pins 9 thru 15 of the PLL from their circuits....by cuttng the trace to the selector switch with a razor blade. Pins 7 and 8 are more difficult. Then mount a 9-section miniature switch(often found on old computer boards) within 3 or 4 inches and wire the nine pins 7 through 15 directly to the switches, left to right respectively. One side of the switches go to +5.4 volts, and the others to the individual pins. They are SPST that only supply +5.4 for logic HI's. The PLL pins pull themselves LOW internally.
It is easy to program a divisor number by starting at the most significant bit (256 on the left-hand switch) and progressively take the biggest bite permitted toward the desired number...noting the running tally and the remaining counts required. It's almost fun, and you have full easy control of counts N= 1 to 512. The final divisor count is simply the sum of all the HI pins and their values. If you choose this option, a 23 channel CB has the same benefits as the 40 Channel.
The PLL also has the nice feature that pin 6 goes HI when the phase-control is locked on (or prevents CB transmitting if it was not HI). This is wired to an additional small transistor to make an LED glow when the frequency is in locked on.
The output of the additional mixer is tuned to resonance (2 to 3 MHz range) and will probably require switching an additional switched-in capacitor to provide suitable resonance for the entire range (or re-tuning of a slug). This project used a SPST (center open) to provide three options: adding no additional capacitance, or two other values for low, mid, and upper range of the 2 to 3 MHz i.f. range. A test point on the DC bias of the MosFet variable capacitor gives a useful indication of the changing DC required to prevent VCO drift, and provides a voltage reading that allows you to set it to the center of its dynamic range using a low-cost LCD voltmeter. These voltmeters are usually available at Hamfests for $10.
There are some CB models that have PLL's not suitable for this project approach (TC9105P in a Motorola 500 series for example), except that its 10.240 MHz crystal oscillator could be used if a substitute PLL is used. NTE-1167 seems to be about the only substitute available along with its data sheet (www.nteinc.com) but at a rather substantial price of $21.(www.mcmelectronics.com).
This modifcation was tested with the bottom of the TR-3 off and the CB circuit board and oscillator/mixer circuitry fully exposed. It drove a kW amplifier with open-wire antenna feeders in the same room, and performs with the same frequency stablity as modern equipment.
Of course the external crystal oscillator (s) must be exactly on frequency. Usually small parallel capacitance, or small series capacitance or inductance, can tweak these on frequency. On 80M and 20M the only other thing than affects the result is the Drake 9 MHz oscillator (C-130), but it can only be moved very slightly, because it must remain centered midway between the two USB-LSB bandpass filters.

(Also
tweaking the trim capacitor in the CB 10.240 MHz crystal has a small effect). But
40M,15M, and the 3 sections of 10M offer a better option by tweaking those crystal oscillators L1, L5, and L2 respectively.

Note that when the VFO is not frequency- locked, or if the CB is turned off, the
TR-3 continues to perform as it did originally except that the dial accuracy will not track as well. The calibrator and the sliding cursor pretty much compensate for this problem. The plastic dial scale can be rotated (to aid calibration) without loosening any set screw as described in the manual. It is secured only by compression, and can be slipped like a clutch.

This project could also be an interesting approach to the five new SSB channels on 60 Meters if the VFO is shunted with capacitance to tune lower (e.g. 3669.5 MHz vfo added to 5330.5 60M channel yields 9 MHz i.f frequency). But 3669.5 vfo is too high for the divider to count. A readily available 6.000MHz (5999.5) crystal can be mixed with the VFO to yield 2330 MHz which is divided by 233 to yield the 10 KHz reference frequency required at the phase detector.
Hopefully, the power amplifier tuned circuits are broad enough, without modification to provide the 50 watts output allowed on 60 meters.

Not sure as of this writing Bill. Fewer and fewer places in the US of A
are willing to ship to Canada. One place I checked before Christmas
had increased the minimum order to Canada to $ 150.00 in US funds.
Some places have no minimum order if the address is American. I
should start polling companies and create a data base of who will and who
will not. We used to have a super supplier in town, but that was
decades ago and was known as CamGuard Supply. You could walk in
and buy one 1/8 watt resistor if you wanted from a fella behind the counter
who knew what you were talking about. No blister packs back then.
Now it takes me days of searching the internet, and days to unwrap the
darned thing when I do get it. No wonder so few new people are interested
in electronics, it's just to hard to find parts.

Ham of 38 years who loves to build things.

Wow - my experience sure is different! The Internet has made parts FAR more available. Used to be you would pour through the Allied catalog making up the list, go down to the Post Office to get a money order, send off the order which included some outrageous shipping charge, then wait one or two months for the parts to arrive. I was fortunate in that I lived across the river from Radio Row, so if I couldn't find it in the catalog, I would organize an expedition into the city. Still, collecting parts for any reasonable sized project was a complex, time-consuming affair.

Today you go online to see what DigiKey has in stock at this moment, order online or over the phone, and wait until tomorrow, or if you're cheap like me, the day after tomorrow, for the parts to arrive. No sirrrreeeee, I'll take today over the bad old days.

Gotta admit, it can be a little frustrating until you've lined up your favorite list of suppliers. But whatever you want is out there.

My list:

DigiKey (www.digikey.com) is generally my first choice. They are not always cheapest, but their prices aren't bad, and their customer service is second to none. (I only learned recently that they were started by a ham, too!) They have an amazing number of parts, although they are pretty weak in the RF department. They also have the best catalog. They do have a $25 minimum order, but that is never my problem .... they have too many goodies I can't live without. Their default shipping is by air, though, so if you're cheap you need to specify ground shipping.

B.G. Micro (www.bgmicro.com) has a lot of unusual stuff. Some of their things are very inexpensive, some pretty high, so you need to know what you are looking for. I like them for cases and LCDs, although sometimes they have deals on something you need, like a pile of zeners or 1000 2N2222's.

W8DIZ (http://partsandkits.com) is THE source for toroids. His prices are amazing and he ships priority mail, so shipping is only three-something. He has a few other assorted parts, and when he does, they are cheap. He sells toroids in big bunches, but even if you need only a few, you can typically get a couple dozen from him for less money you would pay to Amidon for three.

Dan's Small Parts and Kits (www.danssmallpartsandkits.net) has more RF stuff than most. His collection is a little odd, but if he has it, his price will generally be on the low end. He only takes orders by snail mail, though, so it's typically a two week wait or more.

R.F. Parts (www.rfparts.com) has, well, RF stuff. If I can't find it anywhere else, I go to them. They are definitely the high-priced spread, but if you need an exotic transistor, you need it.

Mendelson's (www.meci.com) is the weirdest. They have a varying inventory of oddball stuff like BG Micro, but their strength tends to be more along the lines of connectors and hardware. They usually have a lot of really weird stuff, though, so sometimes you discover something you can't live without!

Someone mentioned www.radioshack.com. They used to be a good source, actually. But recently they have cut back to only what is in the stores, and at the same prices, so they are off my list.

I have found that copperclad, hookup wire, knobs and tools are best left for the hamfests. You can get them, but they tend to be pricey online.

We have two Radio Shack stores here in town, and both of them seem to be carrying more parts than they used to. They have hidden most of them in those little drawers, but there seem to be more there than there used to be. At least they are easier to find.

Still, because of the price, they are my supplier of last resort!

No affiliation with any of these guys, of course.

Larry, I have been buying electronic components from Radio Shack for 40 years, and I can't say I got any that were complete c***. They all worked, isn't that what you get them for?
Radio Shack doesn't manufacture any of the parts they sell, they repackage OEM parts and resell. They cost more, and the people working there know little or nothing about the parts section. But the parts work.
As another poster pointed out, they are mighty handy for the odd part to meet some deadline, or if you are just trying to finish your latest weekend creation and need a 1N4007, and a 10k 1/4 watt in a hurry. I would never use them as the major parts supplier for anything but the smallest of projects. I would consider them getting out of the parts business a loss.

Well, I guess it is who you know..all the ones that I know that have been fixed here have bought thier cars or trucks new and Ford was glad to help them. They also knew ahead of time that the buyes were hams and planed on installing

radios in the cars or trucks.....

Tell the dealer to look up Ford's technical service bulletin
TSB 93-15-6 and/or TSB 95-11-3 (I believe the latter is an updated
version of the former). This describes the problem, identifies the
Ford filter part which is to be installed inside the fuel tank on the
pump wiring, and describes the procedure.

This is reportedly _not_ a customer-installable fix. As it involves
removing the fuel pump from the tank itself, and modifying wiring in
this area, I'm not too surprised that Ford would be very reluctant to
encourage vehicle owners to attempt this on their own.

Randy,

Ford has had a service bulletin out for several models about the fuel
pump noise. http://www.arrl.org/tis/info/pdf/W1MG.pdf have a look at
the url, it tells about your fuel pump noise even gives diagrams and
suggested time to install the filter for a qualfied mechanic.
I found out about it when my 1996 Ford Ranger was still under
original factory warranty. The ford dealer added a fuel pump

electrical filter to the fuel pump in the fuel tank. Can't say it did
a whole lot of good though, but is better than it was before they
added the filter.

Who makes the coaxial caps you used ?

I have been pondering this idea on and off, but can't tell if it would be worth the effort to do something like this. Can you make a decent living selling small quantities of parts - passives, crystals, oscillators, solid state, IC's , even exotic things like back diodes and mmic's - via mail order. Or, do the large parts houses like Digi Key have the field sewn up?

Reed, Digikey has a warehouse in Winnapeg that they service Canada
from, also a catalog with Canadian pricing on line.

http://dkc1.digikey.com/ca/digihome.html

There is a $6.50 handling charge on orders less than $32 something
bucks, plus shipping of course. I've used them a few times, they ship
purolater, it arrives within a few days. of course, you could drive
down to Dartmouth & give your buisness to RAE or Jentronics but they
probably won't have the stuff you want in stock anyhow.

Not the perfect solution but this is the world we live in -

We have a few companies like that here in the UK. They have been going
for years so they must be doing reasonably well.

They don't have very extensive stocks, but they are very useful for
small quantities of standard parts as they don't charge much for postage.

This is exactly what I was thinking of in my earlier post, and close to what I'd design if I were doing it.

If your recevier covers 26-30MHz then you might want to use a 24MHz crystal -- your LO frequency will be closer to your output frequency (which is bad), but (a) you cover the whole band and (b) you can get a cheap microprocessor crystal. You could also use a 32MHz crystal for output from 18-22MHz, or just dig around in your junkbox for whatever crystal you have on hand.

There are several small outfits out there, Dan's Small Parts and Kits and KitsAndParts.com come to mind. I've chatted with the owner of KitsAndParts.com from time to time, and I get the impression that you need to buy huge quantities (and obviously sell them) to make it worthwhile. I'm sure that for more "normal" things, it's going to be hard to compete with DigiKey and Mouser. But there are a lot of things that are hard to find, and I could imagine there is a niche there if you could find it.

KitsAndParts tends to specialize in toroids, and whatever he can get a deal on. Dan's favors popular RF things that QRPers need. The trick, I suppose, is to find something that DigiKey doesn't supply that is in demand, and that you can become known for. Face it, for any project that I can't stock out of my junk box, I'm probably going to write an order to DigiKey. If they have something, you are going to have to be a whole bunch cheaper to justify my writing ANOTHER order and another shipping charge. Probably you can't do that, so your only hope is to have something that they don't have.

Once you have decided what they don't have, now you have the problem of being in my face so that I think of you. The way to do that is to have some category of stuff that you become known for. Dan's tends to have RF transistors, varactors, etc. In addition, he has lots of stuff I could get at DigiKey, but it's cheaper at Dan's. Once I figure out that I need a varactor and I'm going to have to order stuff from Dan's, now I'll order all sorts of stuff there because he's going to be cheaper than DigiKey. He's not enough cheaper to get me to order something I could get from DigiKey if that was the only thing I needed, but once he has hooked me with something that I can't get, then he gets orders for a bunch of other stuff, too. KitsAndParts is pretty much the same.

So what's hard? Medium power RF transistors come to mind, as do MMICs, mixers, variable caps. Seems to me there *should* be a cheaper place to get cases and knobs, but that is mostly a price thing. But I wouldn't spend a lot of energy with stuff you can already get easily. You are going to have to be a LOT cheaper, and that is probably hard.

..

Don't know if it's of any help but I buy items on-line, by phone &
locally and what I look for in all suppliers are:

1. Useful stock
2. Good price to me at SIT (soldering iron tip)
3. Someone at the other end who knows what they are talking about, the
help full suggestion of a suitable alternative that is in stock, or even
an alternative supplier for the really tricky one would always earns a
return visit in my book. If I get good service I don't keep it to
myself.

Good Luck (and don't forget your potential overseas customers !!).

Really? That's quite odd. I've never had a problem with any
disputed charge on any of my cards. They've always been settled
to my satisfaction basically with one call to the credit-card
company.

348. Good Receiver for a 10-year Old

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-15 06:22:04 UTC
From: Tim Wescott <tim@wescottnospamdesign.com>

Body handling: Inline uuencoded payload not displayed: Tim Wescott.vcf

Does anyone out there have recommendations for a good, simple receiver kit for a 10-year old budding ham? My son just fell in love with the Neophyte receiver from ARRL's "QRP Classics", but chasing down parts is going to be a bit of a bother (the coils _are_ still available from Mouser, and FAR circuits has the board, but it looks like I'm going to have to donate a couple of my precious tuning caps). If it were me I'd just start building and accept the necessary futzing around; with him I'd prefer something where all the parts fall out of the box and go together quick before he loses patience.

Ideally there's someone out there that makes an improved Neophyte kit. If I have to I'll buy one of the new kits that are mostly pre-made surface mount with a bit of through-hole soldering of the tuning pots and whatnot, but I'm not sure he'll get the feeling of accomplishment that we're looking for.

Any suggestions?

Thanks.

Hi Tim,

Good to hear another lad getting into the electronics hobby :-)

In the ARRL Radio Amateur's Handbooks that I have, there is a little
direct-conversion receiver in their. Simple to build and is quite the
performer :-)

Thanks Jacques and Gregg. The Hobbytron receiver is a Ramsey Electronics kit that (from the parts list) looks like a knock-off of the Neophyte. While it may not be the best RX in the world it'll be complete and he can probably learn to solder _and_ have a radio when he's done.

Just got back inside form the minus 42 (wind chill temperature) degree outside.
Tried a local electronic repair place in town and found the lamps I was looking
for.
Also found that they sell other electronic stuff. Nothing on display, one has to
ask
at the front counter, but what the heck. At least I now know they have parts
and will sell in lots of one, or more. :-)

Hard to believe just how small some lamps can get. Grain of wheat, grain
of rice and grain of sand. The one in my digital watch is so small it looks like

a swollen spot on a piece of human hair.

Way back, when I was 7 or 8 years old, (I am 55 now), my dad got me an electric train set....During that Christmas we were at my Grandparents place and they were on 25 hz power....At home we were on 60 hz power...

We had to be at home for me to try out my new train set.

What has that got to do with this question?...

This....

I have a number of transformers and would like to experiement using then at a higher frequency....let say 500 hz and / or higher.....

Would they still work?...I am assuming so...

Would they run cooler?....

Could anyone foresee any negative effects?....

Behold, larry signalled from keyed 4-1000A filament:

> Would they still work?...I am assuming so...

Yes.

> Would they run cooler?....

Depends. If the core is of good quality then they'll run cooler. Eddy
current effects are more pronounced at higher frequencies.

> Could anyone foresee any negative effects?....

You may get higher than anticipated secondary voltage.

Yes, it is amazing - the sizes - isn't it. It had been a while since I ordered those bulbs and I only needed them that one time, so I couldn't recall the exact name. Matter of fact, because they had burned out so soon, I think I bought 3 sets. I figured that would be about the life of the radio - which I had won at a Hamfest. It seems to me, that must be an inherent defect with the 212 RH or at least some of the models. I know several who had to replace them after a short period of ownership. I don't think my radio was 2 years old. And certainly, when I was away at work or whatever, it wasn't on all that time. So it "seems" to me, the run of bulbs they had were apparently defective. Mine that I installed have been in there since. I feel bad for a friend of mine, he sent his to Yaesu to have them replaced. Ouch! Before someone may say mobile abuse, mine was used on a desk. They still burned out probably far faster than they should have. I'm not aware of any "life" of those as compared to say lights for your home with say a 1000 hour life. Glad you were able to find a parts source nearby, it sure helps! SM

If you want to determine if a soundcard is physically installed, look
at the back panel and look for line-in, line-out/speaker and mic
jacks. Looking in Windows control panel, device manager will tell you
if the drivers are installed and allegedly operational.

I'd try them, but cautiously. Running a 60Hz transformer at 500Hz will mean that you have a higher unloaded inductance (good), a higher leakage inductance (bad), lower peak flux in the core (good), higher eddy current losses (bad), etc., etc. The eddy current losses are what will get you in theory, but in practice the smaller power transformers have laminations that seem to be thinner than necessary as a matter of constructional convenience.

Hook it up, try it out, look for sparks, smell for smoke, and after a while put one of your less-valuable fingers on the core and see if it's getting hot.

Back in the days of tubes it was common to see a moderate-power line transformer used as an output or a modulation transformer. If that's what you're thinking then search around on the web -- I recall a pretty comprehensive article about converting a power transformer to an output or modulation transformer (I can't remember which). I'm too young to have actually done this, but if this is what you're trying maybe you can find the article.

Hi Richard.

If you do decide to use a switching supply, the diode
or diodes in the output of the switching circuit may
me be all the reverse voltage protection you need.
Make sure that the output smoothing capacitor can
handle any voltage it is likely to encounter.

A crowbar and fuse will protect against overvoltage.
A hefty Thyristor (SCR or whatever they call them now)
or triac makes a good crowbar.

362. Isolating shorted PCB component ?

Newsgroup: rec.radio.amateur.homebrew

Sometime ago I think I recall someone posted or wrote an article on a neat way to isolate a shorted component on a pcb using common test eqpt but I can't recall the methodology. I'm trying to find a shorted component on a Wavetek 188-S-1257 signal generator. The B+ line reads about 0.4 ohms and I'm not having much luck disconnecting componets. I don't have a schematic and my eyes ain't what they used to be for tracing and I want to minimize the unsoldering. Does anyone recall the article or have a good way?

I've used an ESR meter to find shorts on circuit boards. The have
enough resolution below an ohm to tell when you're getting closer to the
short.

365. Re: Isolating shorted PCB component ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-15 20:36:47 UTC
From: Bob Shuman <reshuman@removethis.lucent.com>
Message-ID: <bu6tl2$mmk@netnews.proxy.lucent.com>
Source record: 29451
Cross-posted to: sci.electronics.repair,rec.radio.amateur.homebrew,rec.antiques.radio+phono

When I worked as a circuit test engineer that produced fairly complex multi-layer PCBs many years ago, there were three primary methods we used to find shorts across the power rails.

1. Use a calibrated micro-ohm meter, fixing one lead to the PCB ground and taking various resistance readings by moving the other lead from the board edge connector along the traces to locate the point where the meter provided the lowest resistance reading. You could then fix the lead to that point and then take readings by moving the other (previously fixed) lead along the grounds to again find the minimal reading. This usually led you to the area of the board where the short or defective component was located. If you had sensitive enough equipment and some good test leads, this procedure usually worked pretty well when there was an actual hard short.

2. Apply a current limited, voltage limited (lower than the nominal design voltage, for instance 5V DC) power source across the power rail at the PCB edge connector. Start with a fairly low current limit and increase this as needed, but keeping the current reasonable (you don't want a defective component to explode - been there done that). We then used either a thermal sensitive plastic sheet (material it contained was like the stuff used in "mood rings" from the 1970's) or an infra-red camera to find the "hot spot" on the PCB. This technique had the advantage of working for soft shorts, such as were created by defective components (transistors, other semiconductors, ICs, capacitors, etc.) or even resistive type shorts that were created by contamination from foreign materials (conductive growths, moisture, salt water contamination, etc.) We were even able to "see" internal shorts on 8 layer circuit boards using the camera.

3. Visual observation and path tracing coupled with selective unsoldering of legs of suspect components (assumes through hole mounting, not surface mounting) and use of isolation rings (small plastic rings that slid over the unsoldered leg of an IC isolating it from the multi-layer solder pad/circuit. This technique was generally used as a last resort and usually in combination with procedures 1 and 2 above, prior to scrapping "difficult", but costly product that had been diagnosed with a power rail short.

The above techniques are what I used about 20+ years back when I had engineering responsibility in a large electronics factory. I'd imagine that there are likely better approaches today due to improvements in technology so would be interested to hear what others recommend.

Good luck!

Bob

Bob Pease gives a schematic for a short-circuit detector on page 21 of his "Troubleshooting Analog Circuits". It uses an LM10 op amp and an LM331 voltage-to-frequency converter, plus one transistor and some passives. You feed some low-voltage, current-limited power into one end of the shorted trace, slide the probe along the PCB trace starting from the power injection point, and listen to the tone. When you go along portions of the trace which aren't carrying the short-circuit current to ground, the tone remains stable. When you go along portions which _are_ carrying short-circuit current to ground, the tone rises (lower voltage present on the trace) as you move towards the short, and falls as you move away from it. When you pass the shorted point, the tone rises to its highest frequency and stays there.

Pease points out that you can use this same basic technique with nothing more than a current-limited voltage supply and a sensitive voltmeter (VTVM or FET-input DVM)... but that listening to tones is a good deal easier.

At .4 ohms, if you feed in 100 milliamps you'll get around 40 millivolts at the injection point, falling to zero at the point of the short. A good 3.5-digit voltmeter with a 2-volt scale ought to give you enough resolution to get quite close to where the short circuit is.

Hi Everyone,
I'm trying to identify the power connector used in the Yaesu FRG-100.
It appears, at first glance to be a standard 2.1mm tubular power
connector but it is actually somewhat different looking a little like
a shrouded coaxial connector.
Does anyone know what its called and where, preferably in UK, I can
obtain one.
There is no mention in either the Users Manual or the Service Manual.
thanks, Mike W, G8NXD qthr

Change all those little tear drop bypass caps connected to the shorted line.
Won't hurt to replace them all, might save a future short. Ken

I'm using a bog-standard power connector, bought at Radio Shack, to
supply power to my FRG-100. I took it in and ran through the sample
connectors until I found one that fit, then bought it, a heavy-duty
12V power supply, a female cigarette lighter connector, and a cord to
go from cigarette lighter to the universal connector that the coaxial
power connector plugs into. Works _fine_

Right now it looks like 2 might be the problem marked AVX 103 and AVX 849.
I'm guessing that they're tantalums but not sure. The Wavetake was mfg in
1989. I need help on the values and voltages. There's too many to just
start changing.
tnx

Use an adjustable DC power supply to feed the shorted power rail. Use
16 gauge, or larger wire to minimize the voltage drop. Make sure to
connect the meter negative to ground at the same point you connect the
adjustable power supply to the bad board. Set the adjustable DC power
supply to about a half amp, and use a DC voltmeter to read the voltage
drops across the traces. You will find a point where they level off.
Back up one part to the last linear voltage drop and you have found your
bad part. I prefer to use a 4ï¿½ digit voltmeter, or better to read minor
variations. Also, check the voltage on the ground buss if the board
isn't bolted to a chassis to find which part of the board has the
problem. I have fixed hundreds of shorted boards this way.

a Hamfest. It seems to me, that must be an inherent defect with the 212 RH or at least some of the models. I know several who had to replace them after
a short period of ownership. I don't think my radio was 2 years old. And certainly, when I was away at work or whatever, it wasn't on all that time. So it
"seems" to me, the run of bulbs they had were apparently defective. Mine that I installed have been in there since. I feel bad for a friend of mine, he sent
his to Yaesu to have them replaced. Ouch! Before someone may say mobile abuse, mine was used on a desk. They still burned out probably far faster
than they should have. I'm not aware of any "life" of those as compared to say lights for your home with say a 1000 hour life. Glad you were able to find
a parts source nearby, it sure helps! SM

Did you ever think about adding a resistor, or a couple diodes to reduce the voltage a little? It will extend the life of the bulb without a big change in brightness.

Seems to me there's a way to use a moderate current and sense the _magnetic_ field. Follow the field around the board along the runners. However, I don't remember what was used to sense the field.

I'd probably try an audio sig gen to get an AC current and an old tape recorder magnetic head...and an audio amp...or let me see. What else is in the basement that can pick up a mag field. Hey! I have a stash of Hall sensors... Probably just about any high micro-henry or mili-henry inductor will do. I'll bet even a toroid will be a good "close-in" sensor. If it is laid right on the runner with the current, it'll probably pick it up. Seems like it would have a short range therefore accurate locating ability.

I was recently playing with a Simpson 60Hz AC current probe (5-100 amps) (made for a 260) and compared it with a small toroid I had lying about. To have something to sense other than 60Hz. I took the output leads of a 600 ohm AF generator and ran one through the toroid then just clipped them together (shorted output generator).and was able to sense it with the toroid (about 1/2 inch dia. about 40 turns on it). Using an o-scope. The higher freqs were better.

However, this has the current going through the toroid center. the best case. Have to see what I can induce with he wire right up against the outside.

HP used to make a hall effect (IIRC) probe for current tracing. One of their
Bench Briefs technotes described the probe and the process.

I wouldn't choose an exciter in this frequency range for use with 6m,
it is already known problems with using 28MHz, so I chose 14MHz for my
6m transverter, and it seems to have been a good reason for choosing
14MHz for 2m converters earlier

SM6DJH once described a way using double conversion for the
transmitter and single for receiver to avoid such problems

30 years ago I was a broadcast engineer at a B&W TV station. The
projector bulbs in the RCA film chain were rated for a 20 hour life at
120 volts, and they were pretty close to that figure. I couldn't depend
on a steady supply, so I adjusted the Variac in each project to run them
at 100 volts, and got over 300 hours out of every bulb after that. The
color temperature was out of spec, but you couldn't tell, because
everything was B&W.

I had good success with a variant of #2 on a very large digital board that had a short between the +5V and ground -- both of which were planes due to the high current and multiple loads.

I energized the +5V bus with a supply set for 1 V and current limited to 10 A. Then went around the board measuring between adjacent +5 and ground points [like across a bypass cap or an IC]. Where I found the lowest drop was the short.

Dr. G.

Here is some info that may be of interest:

IMPROVED NEOPHYTE RECEIVER

This receiver was featured in the spring 1994 issue of Ham Brew
Magazine
Designed by Wes Baden, K6EIL

This is a nice 40 meter receiver and uses a NE602AN OR NE612AN mixer
chip
and incorporating an AF pre-amplifier and bandpass audio filter
will drive a 2 1/2" to 3" speaker to room level volume.
Kit includes etched circuit board and all board mount components
included is a very nice 20pf air vairable capactior..double bearing
type
has built in 8:1 reduction and 1/4" shaft
copy if artical included with kit...price of this kit is...$32.95

You can find the site where this is offered by doing a Google search
of "Dans Small Parts and Kits."

Ten-Tec also has a kit in their T-Kit series that sells for $29.95 and
comes with all of the parts to put it on any band from 80 thru 10, and
this also has an audio filter that works quite well. The Ten-Tec also
has a very fine instruction manual, so that would seem to be a better
kit for a kid.

Hope this is of some help.

Do you know where I could find a copy of the Ham Brew article? Is it on the
web someplace, or does Dan's include instructions?

I didn't think of Ten-Tec -- when I hear Ten-Tec I think "really expensive
American made radio", not "good cheap kit". That is my problem and no one
else's, of course.

The tantalums in WaveTeks were the weak links. I was continually chasing
shorted tantalum bypasses when I owned two WaveTek 3000 signal
generators.

<snipped>

I have a question, has anyone built the above and had success with it? A friend of mine built a kit once from Ramsey - it used a NE6XX chip and the receiver was the biggest piece of garbage I had ever seen. He built it right, I and another person checked his work and tried to get it to work for him, that thing had NO EARS! A WASTE. It had some audio, but it sucked for volume and that wasn't counting the static when "trying" to receive. He called Ramsey to complain, they wanted a bit of change to correct it for him.. The kit was about $30 to start with. In the end, he would have had about $80 or so tied into a crappo receiver. I'd hate like hell for that kid to be disappointed when he is done. I know I've been down that road and it sucks. That can sure suck the interest right out of a newbie real fast. I'm not saying the above mentioned design or circuit is bad. I don't know, I've never tried one. All I'm doing is comparing the similar - even if only in the chip used - design basis. I don't want to see the kid crushed by a non working unit. Even with the Heath Kits, some times, there were defective components or so on. Eico too. I hope the father or whoever - is prepared to help the boy along and EXPLAIN any problems up front so the kid isn't blown away to the point of saying to hell with it and quitting if the item doesn't work. Some soldering practice would be good too, if he's not done any as yet. SM.

Usually if the transformer was designed for a low frequency it will work at a higher one tuil the frequency is so high you run into core losses. If a transformer is designed for a higher frequcncy it will overheat if ran on a much lower frequency.
The military used to use about 400 hz AC in the planes so they could save weight on the transformer cores for one reason.

That is what I usually think also. I did put together their 6 to 20 meter transverter several years ago and it seemed to work fine for me. Receiver converter part was very sensitive and I received good audio reports from it using a Yaesu 757 lowband rig.

Hi All:

This is KD6NRP in southern California. I maintain a web site (www.spacearchive.info) that covers astronomy and space news for California, Arizona, Nevada, Utah, and New Mexico.

Besides publishing stories about what NASA and universities are up to, I'd like to begin adding news stories about space-related amateur radio activities and events in the Southwest.

Here are some of the activities I'm interested in:

- High altitude balloon flights

- High altitude rocket launches

- Amateur satellite construction/prelaunch preparations

- Meteorscatter comms during meteor showers

- Extensive VHF openings due to aurorae, etc.

Please let me know if you learn of any such events.

Some questions. How are you going to position it against the trace
accurately? What about double sided, or multilayer boards?

The problems with using AC to find shorts is that you get false peaks
and dips from the inductance of the traces, and the characteristics of
the components. Another problem is that some parts self destruct with
only a small reverse voltage so you can damage a lot of parts while
troubleshooting the board.

I used the DC voltage drop & sensitive digital meter method on boards
that people couldn't fix with AC, then had to find the parts they
damaged. The whole idea is to find and fix a problem quickly, and
reliably.

==========
Question : Is the Ten-Tec 6m transverter also available for 28 MHz e.g.
RX : 50 --> 28 MHz ; TX : 28 ---> 50 MHz
or can the 14 to 50 MHz transverter be readily modified for operation
from a 28 MHz base unit ?

Reason for the above question : I have an old (but almost unused) Yaesu
FT901DM HF transceiver with a FTV901R transverter with 2m and 70cms
modules but without a 6 m module.
The system works through the HF transceiver's 28 - 30 MHz band . In
Europe the 6m band is from 50 - 52 MHz.

TIA for any advice.

Frank GM0CSZ / KN6WH based in Scotland.

Hard to believe just how small some lamps can get. Grain of wheat, grain
of rice and grain of sand. The one in my digital watch is so small it looks like
a swollen spot on a piece of human hair.
==========
When having to replace 'tiny bulbs' consider conversion to LEDs . These are readily
available (also the high intensity ones).
Although you might have to add a resistor ,they will last forever .....or at least a
lifetime.

==========
Running transformers on a higher freq is fine provided the core can manage
the higher freq.

During the valve era ,aeronautical radio equipment ran on 400 Hz resulting
in smaller and hence lower weight transformers.

However running power supply transformers at an AC frequency lower than the
one they are designed for might cause the laminated core to overheat.

In practice : 50 Hz transformers meant for use in Europe and elsewhere can
be readily used in the US and Canada.
However transformers designed for 60 Hz having 'marginal cores' could
overheat when used on a 50 Hz supply.
So equipment with 'wallwarts' purchased in the US ,(apart from being
suitable for 117 V only) I never use on a 50 Hz supply system.

Nowadays with much equipment having a switch mode power supply , the
frequency / voltage problem no longer exists.

I have a relatively ancient Roland single-pen XY plotter (B-size, or 11" x 17") that has been sitting in the hangar wrapped in plastic for at least 15 years. It was at one time the top of the line and is accurate as you can make the pen line. It uses india-ink pens, and as I recall, you can use a regular KohInOor pen in the holder. The language is either Roland or HPGL. As I recall, it used the parallel port and also had an RS-232 interface, but I'm not sure about the serial port part. It sits flat on a desktop.

When I packed it up it worked perfectly and I believe all the documentation that came with the unit is still with the unit. I'm not saying that 15 years in a hot/cold hangar hasn't taken its toll, but you can't beat the price.

It is free with one caveat: You have to pick it up at Grass Valley CA airport over this weekend. No shipping. If I have to ship it, I'll list it on ebay come Monday morning and make a few bucks on the deal for the hassle of packaging it up. Free until then.

I'm headed out right now and won't be back until this afternoon, but if you want it, or can have one of your friends from the Sacramento area pick it up for you, email me jim@rstengineering.com and I'll email you back -- first postmark, first served. Please don't call -- the person answering the phone will have absolutely no idea what you are talking about.

The father is an electronics engineer who has experience with receiver design and construction, so debugging isn't a problem. We _do_ need something that's going to go together easily without a bunch of futzing around (and without dad doing "minor" redesigns that "only" add a month to the construction time).

If it lives up to it's spec sheet the '602 should make a good receiver, I know it's in a lot of designs. It has a reputation that matches it's spec sheet -- it has good noise performance, lots of gain (which is nice in a DC receiver), and a mediocre 3IP (which is to be expected for a low-power device with high RF impedances).

We could probably throw something together from parts that I have in my shop, which would be fun for me. Unfortunately new designs never work right the first time, and you don't develop the joy of a good debugging session until you've been primed with some easy successes. I can see him watching me have fun for about 15 minutes then wandering off to play on the computor.

So the Neophyte has everything I want: It's simple, so it'll go together quick; it's through-hole, so he can solder it without use of a microscope; and it should actually be useful. The Ten-Tec has even more, because it has RX muting, which will come in handy if I loan him one of my QRP transmitters.

The 20 to 6 meter converter is made to operate in the low end of 6 meters.
The US band is 50 to 54 mhz but TT does not recommend operating much above
52 mhz with their transverter.
They do make a 2 meter to 6 meter transverter so you could run you equipment
and feed it to the trtansverter to get on 6 that way.

Converting from 10 meters to 6 meters is not done very often as it is
difficult to keep the 2nd harmonic of 10 meters out of the 6 meter output.
By changing crystals and a few tuned circuits I don;t see why you could not
make the converter work with a 10 meter rig. It might be difficult to
filter out the 10 meter signal.

Go here and look at their products.

http://www.tentec.com/

I was having trouble reducing the lowband rig output to 5 to 10 watts needed
by the transverter. I finally designed a hard keying circuit and also
bypassed part of the transverter padding and fed the low level (milliwat)
signal into the transverter. It worked fine by doing that and no worries
about blowing out the backend of the transverter.

Excellent answers from others. I'll add that I faced and
fixed fuel pump the problem on my '91 Marquis - but that
was on 2 meters. Dunno if my fix would have prevented
the noise on HF as I didn't run HF mobile.

Anyway, I installed a BIG (physically) feed through
cap in the trunk in the + line to the pump. I also
installed a couple of .1 uf (as I recall they were
.1) caps - one across the power leads at the rig,
and one in the blower circuit. I was getting noise
from that too. That one was easy to isolate, as the
noise was there with the engine off and the vent/AC/heater
blower on.

My experience is not representative, and it was to
solve hash on my 2m/440 rig. A cap *in* the tank
should be more effective, in my view. But I figure
the more you know about these *()$%# noise problems,
the better off you are.

Ralph , Tnx vy much for your prompt response.

The said Yaesu FTV901R transverter has a slot for a 6m module.

From the manual ,it works with a 22 MHz crystal for the 50 - 52 MHz portion of the band.

The manual states that the transverter includes a 'selective passband filter which effectively eliminates spurious signals', probably including the 2nd harmonics of 10 m you referred to.

I found another 28 to 50 MHz transverter design in a rather authoritative book : 'The VHF/UHF DX Book' edited by Ian White ,G3SEK

What I would prefer doing is to build a 50 MHz transverter to work with the FTV901R ,making it a neat 3 band package.

Another advantage is that the matching HF transceiver has a separate low power output to suit the transverter with the one I have already having the 144 -146 and 430 - 440 MHz band modules,which are the bands allocated to amateur radio in ITU Zone 1 ,which includes Europe.

Again , tnx for your response . As always I find the amateur radio homebrew NG a stimulating forum for enthousiasts.

The Ten-Tec 20M-->6M converter can be easily modified
to 10M-->6M. I have done that and it works fine.
Essentially, you change the LO in the transverter
to 2 selectable LO's - one at 22 MHz, the second at 24
22 + 28 = 50; 22 + 29 = 51
24 + 28 = 52; 24 + 29 = 53

You need 2 xtals and a few components to change the
bandpass filter after the LO to 22-24 MHz
The xtals can be selected via relay or diode
switching. With a simple homebrew outboard filter,
the thing is pretty clean, according to a friend.
I never used the filter or put mine on a spectrum
analyzer, so the cleanness of the signal is hearsay.

404. Your pocket portable PLL non-DX AM/FM radio these days

Newsgroup: rec.radio.amateur.homebrew

Went into a shop today and tried a small (5" x 3"x 3/4") PLL AM/FM portable. Tuned to a local AM station. Audio excellent for the size of speaker. Tuned up 9Khz and station still there, very much audible, with a bit of splatter. Tuned up18Khz from station, station still audible, but much slatter. Gosh, they make the AM filters wide these days don't they in your pocket portable!

I suppose that in practical use as a non DX radio, the wide bandwith has little significance. Not likely that another favourite station is going to be within 18Khz. Audio quality over selectivity obviously. You feel that the radio you are listening to is a peice of junk because of the wide bandwidth, but I guess not, if it gives such good audio quality for such a small size.

I found the bad tant cap, it was a 22 ufd, 20 volt, not any AVX but a yellowish tan blob with a big L. I replaced it with an electrolytic. I found it using my Fluke 87 that measures to the nearest tenth of an ohm and only the suspect cap would flicker between 0.3 and 0.2 ohms, all the rest were 0.4 or 0.3. Now I'm kicking myself for not buying an HP meter that could read 1/100ths maybe 1/1000ths because I could see no use for it. Now I can see a use and one is on my list but nevertheless my Fluke saved a lot of desoldering. The Wavetek still doesn't work as something else is keeping the voltage low and I think it might be a regulator. Now I wish I could find a schematic for the Wavetek 188-S-1257, as it would keep me from wasting so much time.
Thanks for all the tips. guys.

I purchased the Ramsey $30 NE602 receiver for my son when he was about 15 years old about half a dozen years ago. It took him about 2 days, without my help (he had a couple simple digital projects under his belt.) It worked perfectly on applying power. Not as sensitive or selective as my Drake, but it was a good teaching kit for $30. Still works and every once and while I take it camping, since it's so light and receives the BBC (African service, since they gave up on North America.) He got his license the next year and has since moved up the food chain (although as with most kids, he's more into the digital than the magic of analog.)

Later I bought the Ramsey 30 meter CW QRP transmitter for myself and I use it when backpacking. I thought this also was a nifty kit. Put this in a tackle box the size of a VHS tape case and also later hopped it up so it puts out about 5 watts.

I don't know if I would try to use either of these for a neophyte ham though, for fear of frustrating someone who also has to deal with operating procedure, antennas, power, band plans, propagation and people on the band who seem to be sending at the speed of light. Your mileage may vary and since every kid is different, I would monitor closely, but not too closely (especially if you're the parent.)

What leads you to believe there are ANY filters in the radio? Sounds like
the BW obtainable easily within the IF and no lumped filters at all.

Well, I tried the toroid and absolutely zip when trying to tightly couple to the outside. They really are well contained fields. It did sense 60KHz well when through the center (It appeared to be resonant since it also picked up capacitively).

Hafta go looking for that mag tape head. I'll bet any ole' multi-turn non-toroid coil could work. Like those used in tube rigs ot older solid state. No shield. 1/8 or 1/2 diameter.

>
> Some questions. How are you going to position it against the trace
> accurately?

First you do some controlled experiments where you put the test signal
through known runners to characterize the given pickup. How to orientate it
& where it picks up from.

> What about double sided,

I don't see a problem. If you get it set up so it detects at sufficient
distance (.070 or so).

> or multilayer boards?

Should still work, but you'll have to follow the target trace by "braile"
(sp) since you might not be able to see it.

> The problems with using AC to find shorts is that you get false peaks
> and dips from the inductance of the traces, and the characteristics of
> the components.

At audio this can't be a problem. I'm convinced it will just be current
defined by the generator.

With a runner short you won't have much current in anything but the
runners anyway, no?

> Another problem is that some parts self destruct with
> only a small reverse voltage so you can damage a lot of parts while
> troubleshooting the board.

Also, there won't be much voltage (remember the DC method?). If you do
have this, you're in risk of burning up runners. That's too much current.
>
> I used the DC voltage drop & sensitive digital meter method on boards
> that people couldn't fix with AC, then had to find the parts they
> damaged. The whole idea is to find and fix a problem quickly, and
> reliably.

Hard to believe a 600 ohm audio gen will blow up anything, but it certainly is possible... of course you just don't go in there blazing away with power..

I don't mean to say the DC method is bad, or that AC is better. AC is just another option, especially if you don't have a good enough DVM. Seems to me I saw a commercial system which did use AC.

My Fluke has problems under an ohm and at fractions of a volt even though it is a 5 digit. Should be good down there. May try it to see how DC works just for info.

Ford has had a service bulletin out for years on several models about
the fuel pump noise. http://www.arrl.org/tis/info/pdf/W1MG.pdf have a
look at the url, it tells about your fuel pump noise even gives
diagrams and suggested time to install the filter for a qualfied
mechanic.
I found out about it when my 1996 Ford Ranger was still under

original factory warranty. The ford dealer added a fuel pump
electrical filter to the fuel pump in the fuel tank. Can't say it did
a whole lot of good though, but is better than it was before they
added the filter.

Henry, dont laugh at this method..it works....read it thru before nixing it.
I have had this happen before too. simply put about 5 volts at 500 mils on
the b+ line, regulated at the 500 mils. Let it sit for a few minutes and
then go looking for the part to be running warm. The part will be
dissipating 5*.5= 2.5 watts of heat. sooner or later the bad part WILL get
warm. It will NOT lift traces unless they are VERY small.
If this approach fails, the next thing I do is go in with a new(sharp)
razorblade and start as far away from the power supply and cut B+ traces one
at a time until the short goes away. This isolates the short to a smaller
area.
Suspect Tantalum caps as they usually fail in this mode of low ohms
shorts...let us know when you find it...Eddie

>Would they still work?...I am assuming so...

Should not be a problem. Designed for 25 Hz operation, they have
a lot more iron in the core than those for 50/60 Hz. That means
they are HEAVY. [it's a mechanical mounting problem only]
>
>Would they run cooler?....

Not any more than audio amplifier power output transformers at
the same wattage.

>Could anyone foresee any negative effects?....

Other than physical mounting places having to be much more
sturdy, no problems at all.

Aerospace electronics went to 400 Hz (and higher "wild" supply
frequencies) some time ago to save WEIGHT. For the same
power handling capability, the core size could be smaller for a
given core flux desnity in comparison to 60 Hz.

You WILL get heating and inordinate core losses and loss of
efficiency of power transfer in trying to use a 400 Hz transformer
at 60 Hz.

You will NOT have any of those problems on getting a lower-
frequency transformer to work at a higher frequency.

For common transformer iron laminations, the upper end of
frequency response...where all the effects others were talking about,
would be above, perhaps, 5 KHz to 10 KHz. Those other effects

would only begin to show up at that limit frequency, getting worse at higher frequencies.

In the old vacuum tube "Hi-Fi" music amplifers, output transformers needed a BIG core cross section to reach down to 30 Hz. The upper end of response was determined primarily by the distributed capacitance of the winding with the most turns, secondarily by the iron alloy of the core. Mutual inductance effects didn't much come into play - regardless of what some instructors talked about in classes to illustrate "points" about mutual inductance. :-)

See my previous post about finding the culprit but I had another problem and it was the 7815 3 term reg which I replaced with NOS and the Wavetek came to life but not great. I measured the 15 volt terminal and it was 23 volts so I may not have much left. I have question on your method. For a shorted component with very low resistance, 0.2 I can't see much heat created since P=I squared R. A short of 0.2 ohms wouldn't dissapate much power and all you'll do is heat the traces, other components and perhaps blow short if you're lucky!

415. Signal-to-noise meter

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-17 00:44:01 UTC
From: LA8AK@online.no
Message-ID: <40088451.102947324@news.online.no>
Source record: 29402

On http://home.online.no/~la8ak/m23.htm I have mentioned a
signal-to-noise meter we used for antenna measurements in UK, suppose
it goes on 100kc/s IF with Racal RA17 or similar receiver, and
measures noise modulation on the carrier.
Since we measrued on constant carrier from other PTP-circuits it was a
steady carrier or pilot to measure, it would also work with AM
broacast stations, provided the IF filter is sharp enouth to cut the
modulation

Wonder if a similar construction can be found, but susing omewhat more
modern devices?

Exactly right. Hysteresys (sp?) losses will go down, but eddy current losses will go up. For most applications it's not clear that there's any change in the overall efficiency.

>> Could anyone foresee any negative effects?....
>
>You may get higher than anticipated secondary voltage.

I don't know why. Where I used to work we used many standard 50/60 Hz transformers at 400 Hz with no change in output voltage.

>HP used to make a hall effect (IIRC) probe for current tracing. One of their
>Bench Briefs technotes described the probe and the process.

It was the HP 547A Logic Current Tracer combined with the HP 546A
Logic Pulser. These worked only with TTL or CMOS circuits. The pulser
would drive current into any point you wanted and the tracer could be
used to follow the current path.

You would set the pulser to put out a continuous pulse train, and then
adjust the sensitivity of the tracer so that it would just trigger on
the current pulses sent out by the pulser. It would thus ignore other
current that was flowing in the same trace as long as that current was
either DC or consisted of pulses which were smaller than those put out
by the logic pulser. I think the logic pulser could put out an amp or
so, but they were short enough that they didn't damage anything.

They work well, but the current tracers are rather hard to come by now
and they are rather expensive when you find them.

The 7815 needs only 3 volts of headroom, so 23 volts is plenty. Any more
than that will be dissapated as heat. Your right that the traces will also
get warm but it's still safe. The other post that advised the use of freeze
spray was a good one too. I have used both...Eddie

I've been given a Conway Masteranger multimeter (think it is a model 639) and would like to get hold of a copy of an operating manual or user guide including schematic. I've been told that it was also sold as a Marconi model TF-2650. A pix is available at the following link:

http://users.netcon.net.au/~lcval1/masteranger_thumb.jpg

Help appreciated -

There have been quite a few good suggestions, but there's a little I can add.

I've successfully found shorts between inner layers of multiple-layer PC boards due to misaligned layers. (When layers are misaligned, plated-through holes -- vias -- can contact layers they're supposed to miss, shorting them.) The method I used was to connect a high-amplitude signal generator (one that puts out a few volts into 50 ohms) of about 50 kHz between the shorted layers. Then, I used a small coil as a detector, connected to a scope. The coil was a few hundred turns on a ferrite bobbin (essentially a ferrite rod), about 1/4" diameter and 1" long. With it, I was able to trace the current from the "hot" signal generator terminal to the shorted via -- the signal drops off pretty quickly beyond the short. The via was drilled out to clear the short, and connections to the intended layers made manually.

If the frequency is too low, the AC current spreads too much on a plane-type layer. If it's too high, it won't penetrate through layers which are over the conducting one. If you're not dealing with multiple, plane-type layers, you could use a higher frequency and it should be pretty simple.

A toroid, as someone mentioned earlier, is a poor choice for a detector, unless you grind a slot (gap) in it -- half of a split toroid would work fine. I tried a floppy drive head, too, but found that it had very poor sensitivity. They're apparently intended to be driven by high current, and at quite a bit higher frequency. The resolution would be good, though, if you put an amplifier between it and the scope. I found the bobbin coil to be adequate.

I used this method quite a number of times. Knowing how to find inner-layer shorts does have disadvantages, though. The very first prototype PC boards for the Tek 11400 series 'scope mainframes arrived at about 2:00 a.m. on the day they absolutely had to be built, and all had inner layer shorts. Guess who got called in to fix them. As I recall, I managed to fix something like two out of the four or five -- just enough for that day's build. The rest had too many shorts to salvage.

The same technique can be used to find shorted components, although some of the other methods suggested might be easier depending on the circumstances and type of boards.

I had a digitally tuned pocket radio from Radio Shack, and after I dropped
it in water, I had the chance to take it apart. It only used IF transformers
on AM, so it wasn't anything much in the selectivity department.

Keep in mind, though, that if the PLL isn't well designed, you will get
spurs and a signal can turn up in more than one place on the dial. In
this case, IF selectivity is not the problem, since the same station is
being converted to the IF due to spurs from the PLL. If you've got a local
station that's stronger than the more distant stations, even the reduced
level of the spurs means that the local station can wipe out the weak station.

I've had digitally tuned AM broadcast radios where a local station will
appear up and down the dial from where it belongs, with perfect fidelity
but with reduced amplitude. But at night when some of the strong signals
come booming in, they wipe out those spurs.

Message-ID: <9_1Ob.239$941.5568@news7.onvoy.net>
Source record: 29409

I am working on a project and need to label a chassis. I have used Microsoft Visio to create a template for the front
and rear of the chassis. I then printed those images on transparent labels. They look nice but I have two problems.
First if the ink gets damp at all it smears and second its difficult to apply the label to the chassis without air pockets
forming. I would like to hear from someone that has done this kind of work and find out whats the best way to label
a project chassis.

shorted

I think he was referring to a 15 volt rgeulator that has 23 volts on the
output indicating it was bad and the overvoltage caused other components to
go bad.

424. Re: Would it be worthwhile starting an on-line parts ordering house?

It seems to me that selling parts alone is not going to give enough margin
for
a home business.

I had been giving this some thought myself, and while I won't ever have the
guts
to do this unless I ever get laid off from my software job (33%
unemployment rate in IT in the US!!!), my personal opinion is to gravitate
to
modules or subassemblies that are needed by hams whose designs are (1)
unprotected,
(2) public domain i.e. results of government research, (3) prior art, or (4)
licenseable
to you for a reasonable percentage.

The more you can add value, the better your return will be.

Good luck!!!

The Eternal Squire

That may have been the sensor, but the article I saw related to tracing shorts.
To that extent, it was environment-independent.

Most HP stuff I've seen works well. Being HP, I'm sure they were expensive way
back then.

426. FX828/MX828

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-17 09:50:42 UTC
From: Leif Holmgren <nobody@nowhere.com>
Message-ID: <40090572.8040801@nowhere.com>
Source record: 29413

Hello!

Can anyone suggest a supplier of the CML circuits FX828 or MX828.
Preferably within the EU. I tried the Swedish distributor but they would
not sell me less than 10, which would be too expensive since I need
only 2 or 3.

If anyone can suggest another CTCSS/DTMF/DCS decoder circuit that could
be another option.

73 de SM4RPQ/Leif

427. Ten Tec 1340 problem

Message-ID: <0baOb.11952$i4.5726@newsread1.news.atl.earthlink.net>
Source record: 29414

Just got a TT 1340 40M qrp rig and cant seem to get it to tune, swr is way up and there seems to be lots of oscillation going on in the rig. Power out is about 5 watts and the reflected power is just as high.
Both long wire antennas tune fine with all my other rigs, except the 1340.
Any comments?
Thanks......Gil

From: Roy Brock <roybro@sccoast.net>
Message-ID: <bubgc2$4kft$1@news3.infoave.net>
Source record: 29415

Hello all,

Just once more trying to find homes for the following:

I have a bunch of heatsinks I'd like to sell. Most are perfect for mobile power amps.
Some have enclosures where the face of the heatsink forms one side (the top) of the enclosure, and wings for mounting on the opposite side (again, perfect for mobile PAs). Enclosures/heatsinks just described are approximately 5.5" x 7.5". I have ten of them.
I have other heatsinks perfect for PAs that are 6.75" x 9.25"; I have four of these.
I have a couple that are a little larger than above, approx. 7.5" x 10.5". One has a single transistor PA on it already; stripline matching, so has to be 2M or upwards.
I also have some LARGE stuff for high current diodes/SCRs (>200 Amp) - mega surface area.
There are also various lengths of raised mount TO-3 style sink.
Lastly (heatsinks), I have a box of smaller (one TO-3) type sinks I will sell as a lot.

I also would like to sell five 2.25A 120-volt variable transformers, superior electric powerstat type 10C.

Make offer for anything you're interested in. If you want pics, just ask and I'll email 'em.

Thanks...Roy Brock

Yes, you can sometimes have serious trouble on 50Hz when the equipment
was designed in a 60Hz area. The problem is simply not enough inductance
in the transformer for the lower frequency (even though the difference
is small).

I recall two examples from my work (in the cable TV industry):
1. Hundreds of 50 to 600MHz outdoor repeater amplifiers, line powered
(via the coax) at 60VAC. Took far too much current, and all the
transformers had to be replaced.
2. Piece of rack equipment. 115V input, multiple output windings. We

simply provided a 240-115V step down when we installed it. No problems. One day, new unit, fuse pops after a few seconds. Mains transformer same part number, but different supplier, also slightly fewer laminations. Current went up from 0.2A to 3A. Not an easy fix.

There can also be a problem with switch mode power supplies, but the problem is not the frequency. It is the higher inrush current when you switch on. Again, cable TV equipment, had 0.25A mains fuse. Regularly popped fuse on switch-on. Took a slow-blow 1A to stop it, although the steady-state current was only 80mA.

I'm not pro-American, but I often think that the world might have been a simpler place if we had all used 115VAC, 60Hz, 525-line TV etc....

Ian.

I've had success with air pockets by using a thin sewing needle
to prick the center of the air pocket and then press the material
against the background from the outer edges of the air pocket in --
towards the prick.

The smearing problem _might_ be solved by apply a second layer of
film over the first. Probably more pin pricking there, too....

I've printed onto overhead transparency material (large enough to cover the whole panel), with the printing reversed, so you're looking at it through the plastic film. That protects the printing. You need to find a suitable adhesive (there are some sprays that work OK), and getting it down without bubbles I guess is just an art. You can put some thin rods under it to space it up, and start at an edge and remove the rods one by one as you work across the panel. It's a technique like people who apply veneer or laminate use.

A different ink-different brand of printer-(or even better, laser printed) might solve your smearing problem if you want to keep using adhesive labels.

It's distinctly more hassle, but you can make a very nice looking panel by getting it anodized and photoengraving the lettering into it. The difficulty these days is locating the photoresist. I've made several thousand panels that way, but have been out of that business for over twenty years.

Cheers,
Tom

I found a good 7815 and installed it and except for the frequency dial being
off the thing seems to work. If I find a manual I should be able to cal it
or find out if the cal is off because of a failed componet because of being
overstressed to 23 volts when it was designed to operate at 15 volts. The
output remains flat from 0 to 4 MHz but the when the dial reads 4 MHz the
counter shows 3.5 MHz. At 1MHz on the dial the counter reads 0.570MHz and
similar readings on at audio frequencies.

My son built the Ramsey "shortwave radio" kit about 15 years ago; he had absolutely NO trouble and it worked like a charm. I designed a little outboard VFO (plans available upon request) which he built and which let him copy CW.

His has been a coded-Tech since shortly after that experience.
(Not particularly active, but licensed, nevertheless!)

I don't know the TT 1340, so I don't know if it has an SWR meter built-in:

If it has an internal SWR meter then check the connections between that meter and the RF jack on the rig.

SWR is a quality of the stuff that comes _after_ the SWR meter, and the frequency of the energy going into the SWR meter. So if you're putting 7MHz into the meter you should get the same results no matter where it comes from. Ergo, the "lots of oscillation" that you're seeing in the rig includes frequencies at which your antenna isn't tuned so well.

Try running into a dummy load, and see if things calm down. If you have a frequency counter or an oscilloscope measure the output frequency. Once you get it figured out with that, go back to running into an antenna.

The way I read it , the 15 volt regulator had gone bad and was passing a much higher voltage as it was not regulating . That was giving 23 volts on the output instead of the 15 volts it was suspose to.

441. Automotive GPS Radio Interfacing for APRS use?

Source record: 29428

I'm a new owner of a 2004 Jeep Grand Cherokee with the optional RB1 in-dash GPS nav radio combination. This particular option has been available for over a year or more for older Chrysler model Jeeps and selected cars.

I looked up the specifications for the GPS-radio unit, http://www.wjjeeps.com/nav.htm#SPEC , and found that the GPS section uses a communication specification called "J1850 bus specification for NAV information" for the data format. Has anybody tried to interface to a unit like the RB1 for use as a mobile GPRS station?

I have found some information on the J1850 bus specification and some hardware at http://www.intrepidcs.com/vspy/ . Has anybody used this for GPRS application? There is some free software available if you use a Palm based PC at http://www.intrepidcs.com/vspy/vspyce.htm for using the network interface hardware.

Problems with the rig shouldn't cause high SWR, unless...

the rig is radiating signals on frequencies other than 40 meters. Which
is consistent with your "...lots of oscillation going on..." comment.

I built a 1320 a few years back. (works like a champ!) Best guess is
that there's a problem with one of the coils in the low-pass filter
coming out of the transmitter power amp. (if I can find the manual for
my 1320 I'll post in more detail tomorrow!) I'd double-check that the
coils you wound there (*NOT* the single coil that sets the VFO range)
were wound properly.

Otherwise I'd say there's some other place where you installed the wrong
part. Double-check resistor and capacitor values against the schematic
and instructions.

Update!

After reading the Ford Service Bulletin, I checked to see if it could be the fuel pump. They said to have radio on and then turn key to on position. The fuel pump runs for about 1 second and then stops. If the noise appears for 1 second and disappears, the pump is most likely the source of noise. I did not get any noise until the engine was started. Therefore, it would appear it is something else such as injectors, alternator, etc.

Dang! So much for any easy discovery and possible fix. Still searching...

The Logic probes and pulsers in this series are fairly easy to find
today, but I had to look a long time before I found one of the tracers
at a reasonable price. Yes, they cost more when they were new, but the
tracers were only about 25% more than the probes. Used, they usually
cost at least twice as much as a probe.

the fuel pump will run for a few seconds when you turn the key on and then stop because it builds up pressure in the line. when you turn the engine over the pump will start up again to keep the pressure up for all the injectors.it will never stop till you shut the car off . it has a return presure valve in the line to return fuel to the tank...bet it is the pump giving you the noise..

I used the decal materials available from Micro-Mark (micromark.com)
with good results. When using these I found is was important to
read the directions, *follow* the directions, and be patient. It took
two tries, but when I was finished I had an extremely professional-
looking panel.

BTW, I followed up with 3-4 thin coats of clear, flat Krylon spraypaint.

HTH,

Steve

I'm not sure what your "transparent labels" are but if they are anything
like decals, I can suggest a way to keept the ink from smearing.

Use a DULL spray fixative available in art stores, possibly the
Michael's chain. Do a "dust coat" (very light spray) on the chassis
and the labels before putting them on. Once they are on the
chassis, overspray again. You might want to finish with a gloss
transparent lacquer.

Too heavy an initial spraying will result in the spray solvent reacting
with the labels and ink. That's why I suggest Fixative...designed
not to react with common art media...if used sparingly. Blair
used to make such Fixative under the trade name "SprayFix."

I've done that for years with art work and with printed plastic cards
that go in the wallet. On chassis, I've done that on aluminum
surfaces that were Alodined or Iridited or chemical-film treated,
then printed directly on the dull lacquer surface with a K&E "Leroy"
lettering pen using some stiff celluloid to hold the lettering guide
and stylus over holes. Ordinary "India Ink" in the K&E pen. In that
case the chassis surface can be sprayed to hold the lettering intact.
That also works with decals of the old kind which are really a
lacquer film base with printing on the lacquer film.

<< s there a way to calculate when an amplifier will block by knowing its IP3? If not, is there any way to calculate the blocking capabilities of an RF amp, such as an LNA? >>

Mike-

I understand the IP3 (third order intercept point?) is related to intermodulation. This concerns when a signal just starts to interact with another, generating additional signal(s). IP3 certainly relates, but I doubt it is sufficient to calculate the point where blockage occurs. Depending on linearity, intermodulation can occur well below a level where the amplifier is blocked.

Blocking is the extreme case. An amplifier is blocked and stops amplifying when it is saturated. One might analyze this condition by considering the maximum peak-to-peak output being equal to the supply voltage. Saturation occurs when an input signal's peak-to-peak voltage exceeds the supply voltage divided by voltage gain. Any higher input will produce the same peak output. In the process, gain for a weaker signal decreases as the stronger signal approaches saturation.

In the case of an LNA, subsequent stages can be blocked even though the LNA is operating in its linear range.

Does this help?

Last Christmas my kids gave me a "Grizzly" mini-mill -- you're right, I can slap something together with acrylic or lexan.

I'd suggest using pieces of Vectorboard (composite glass stuff
normally used for prototyping) instead of acrylic on hot power
transistors. Acrylic melting/softening point is rather low.

There was a neat little touch on the Circuit Specialists ready-made
power supplies (I just got a triple unit, excellent buy). There is a
conventional finned heat sink on the back for the power-handling
series regulators. The manufacturer (Chinese) added a simple U-
shape of black anodized aluminum that fits in the "slot" of the
heat sink. That covers the power transistor cases and doesn't
appear to lessen the heat-sinking. Very simple addition to the
standard big extruded aluminum heat sink which has been used
for at least 4 decades. Nothing more than a U structure whose
width is cut to fit the heat sink center area. An aluminum strap
with two little legs at the ends.

I have an Epson Printer with the ability to print on CD-ROM's. This ability can be (ab)used to print directly on any flat surface including the aluminium front panel for projects. The result is excellent.

Source record: 29348
Cross-posted to: sci.electronics.repair,rec.radio.amateur.homebrew,rec.antiques.radio+phono

When I got the 188 the 7815 output was nearly zero and I assume the shorted
tantalum caused the low voltage. After I found the bad tantalum and
replaced it the 7815 voltage was still very and the output pin to ground
mesured 12 ohms. I had a NOS Radio Shack 7815 still sealed in its package
so Iused it and that's when pin 3 went to 23 volts and that nearly made a
grown man cry because I thought I fried addtional components. The PCB was
running too hot. After getting a known good 7815 the B+ stayed at 15 volts
and the unit runs cooler and seems to function except that the dial
calibration is off. I'm trying to find a manual.

I would say not, at least in the US. Digi-Key is scary good, and there
are plenty of other vendors (from Jameco to Mouser to Circuit
Specialists to Mini-Circuits to Newark...) for the cases where Digi-Key
doesn't come through with the goods.

Good point -- clear acrylic would look really pretty, until it melted.

If you insulate the transistor with nylon shoulder washers rather than nylon screws (this is recommended for large temperature excursions, buy the way) then you could use an aluminum shield, for that matter.

Yes most used AM stereo demodulators but those IC's might not be sold anymore.

There must be reasonable implementations as many shortwave receivers have sync detectors.

I just need one to demodulate AM.

Have you heard about the new CDROM burner that uses special blank
CDROMs that you flip over after you burn the data, then the laser burns
the label into the top coating of the new type CDROMs? I think it is a
H-P design that is due to hit the market in the next couple months.

Hi,

I made a simple PIC-based keypad for the FT-817.

With a 16-buttons keypad it makes you set the frequency, change mode (AM/FM/USB/LSB/CW), VFO (A/B), repeater shift (+/-/simplex) and split.

You can find the project on my website at http://www.qsl.net/it9xxs

The firmware for the PIC is free to any amateur radio operator, for non-commercial purposes only.

Best 73s,

Giovanni IT9XXS

Do a search under KE9OA. Pete is developing a sync detector for use with a
MW RX they are going to market. May possibly sell the sync board separately.
In talking with Pete, and having built my own sync detector- few parts and
sync detectors that stay locked and retrieve hi fi audio do not go together.

It's horses for courses....

If you are taping, drilling or using hole saws on 300 series stainless
steels try Rocol RTD compound,
I have not found anything better.

For lath suds Castrol Hysol EP has worked well for me on stainless and
general purpose work.

Vaughn,

It's quite easy: your best bet is the maximum length of wire you can keep
in your backyard AND as high up in the air as you can afford (trees,
towers, chimneys etc.)

To prevent RFI and TVI, make your antenna symmetrical. Feed it with an
open line, and connect the open line with your TX with an appropriate
coupler (the ARRL Handbook is a good source for information).

Please note you do not need to use a thick gauge of copper wire. Even a
thin gauge of stainless steel wire will do.

You will be pleased very much by the results !!

A long long time ago one appeared in the user-contributed circuits
section of Electronic Design magazine. Don't remember the name of the
column but it was always good. They also used to publish circuit
collections from the column every few years. Lots of clever ideas:
"Build this quadraphonic stereo receiver with a single CMOS interter"
is just a slight exaggeration. I remember reading the magazine up to
the early 90's. Don't know what happened to them.

The synchronous detector used two analog multiplier chips and as I
recall was contributed by someone with a callsign. Don't remember any
other details. Anybody remember the magazine and the column?

Thanks and 73,
Jim

479. what will plug into a Fluke 87's test-lead jacks?

ANy EE's out there that remember their circuit design course work. I need the general solutions for L-net, Pi-net and T-net, including reactive loads.
I have cobbled together solutions for these but am not happy with what I have.

General forms in Z would be nice then Fortran can solve them.

A vexing problem. Any inductor in the soultion will have a series R term.
This R needs to be subtracted off the Source or Load and then the calculations run again!. Anyone figured this out ?? Precision is a requirement.

Pat W

It probably uses 4 mm plugs, they are widely available.

Ordinary bananna plugs work just fine, as long as you don't mind them not being sheilded. The extra ring-shaped hole in the thing is for the plug shield which is optional if you're working with low voltages.

I have no idea if this is a possibility, but OEM type GPS units typically
have two modes. One is their internal data format and the other is the NMEA
standard. I know that the Motorola Oncore units do & I have seen reference
to other "OEM" standard formats. On the Motorola units, it takes a command
into the serial port to switch between them.

You kept saying GPRS. I think you meant APRS, no?

489. Eagle PCB layout question

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-20 00:10:55 UTC
From: Paul Burridge <pb@osiris1.notthisbit.co.uk>
Message-ID: <66so00hf4vpmbpp2bc7holvtvrdb9fugsf@4ax.com>
Source record: 29376

Hi all,

I'm just playing around with Eagle Lite this evening and cant seem to get the thing to connect up components in certain circumstances. I get a "this bit isn't a member of that bit" type of error message and the program just refuses me to make the connection. Any ideas?

Secondly, I see that Autorouter is disabled in the Lite version. Does that mean that the main benefit of using layout software is denied me?! I mean, I can spend a few hours making up my own component footprints in any old drawing program and position them as I wish. What use is Eagle Lite in that case? Or is there something I haven't grasped yet?

Thanks,

p.
--

My opinion is worth what you've paid for it.

If you're talking about what I'm thinking you are, you can buy normal
banana plugs at almost any electrical type store like Radio Shack.
You just take them apart, solder your wiring in, and you're done.

I believe I saw an error of that sort, if I tried to create a
connection between an individual link, and a multi-signal bus. You
can only do this if the thing you're trying to hook up, has a name
which matches the name of an element of the bus.

>Secondly, I see that Autorouter is disabled in the Lite version. Does
>that mean that the main benefit of using layout software is denied
>me?! I mean, I can spend a few hours making up my own component

>What use is Eagle Lite in that case? Or is there something I haven't
>grasped yet?

Hmmm. On the version of Eagle Lite Freeware (Linux) that I have on my
laptop, the autorouter works just fine.

I started with a small battery float-charger schematic I had sitting
around, did a "switch to board", let the program throw the components
down off-board in random locations, dragged the components to the
board and then rotated them to minimize the amount of
signal-connection crossing. I then used "Tools/Auto", approved all of
the defaults, and it routed the whole board in about ten seconds.

You _did_ create both a schematic, and a board layout, as part of the
same design? All of the components fit within the outlines of the
largest board that the Lite version will create?

For Sale NEW 7036 (6BE6) tubes.
The boxes have the following information on them:
5960-00-074-4833 ELECTRON TUBE
1 EACH DLA900-82-G-0017-005
A-3/83 GE-7036 GENERAL ELECTRIC CO. Tubes are 5 to a sleeve.
The 7036 is electrically the same as the 6BE6 but it physically
taller. It is the same height as a 6AQ5 so tubes shields will
not fit from a 6BE6.
$10.00 per sleeve plus $3.85 priorty mail shipping U.S. locations only.
1-4 sleeves $3.85 priority mail shipping
4-8 sleeves $7.70 priority mail shipping
Thanks Larry WA9VRH

>what I have.

[why do I sense a student needing help on an assignment? :-)]

>General forms in Z would be nice then Fortran can solve them.

I have them handy for the two-element L-C matching network, including the range of values possible with the two basic configurations of R-load higher-than or lower-than R-source. Reactance of the load can be cancelled out via the match network opposite reactance...one type may require an Z to Y (and vice-versa) transform in order to "see" that.

Before going into all of that, the load impedance (or admittance) has to considered and known approximately. Loads, whether of an antenna or a following stage, all have great variations, especially in reactance values. The choice of network will be governed by the necessary bandwidth as well as range of R and X.

Reg Edwards ought to have a program on his website that does the solution for all those networks. He has a lot of good, useful little programs that don't take up much space in the computer and have good accuracy.

>A vexing problem.

Not if you know complex arithmetic rules. It's just a lot of work in solving equations with complex quantities.

>Any inductor in the soultion will have a series R term.

Not necessarily. Only if there is an inductor with very low Q in the circuit. For most impedance magnitudes of 500 Ohms or less, the inductive loss can essentially be neglected. Once the approximate values are found, the matching network losses can be examined in detail to determine heating and/or efficiency.

>This R needs to be subtracted off the Source or Load and then the
>calculations run again!

No. The solutions can be done simultaneously in the computer...
or reduced to two equations for calculation on a scientific calculator.

>Anyone figured this out ?? Precision is a requirement.

Okay...that sounds even more suspicously like an assignment... :-)

Yes, I "figured it out" some while ago and can do precision via my
FORTRAN compiler program to 14 digits. My H-P 32 S II does
things to 10 decimal digits. Couldn't even come close to that kind
of accuracy in real, practical parts. :-)

If you were actually building something (that's why this is called a
"homebrew" forum), I'd supply the formulas. Those aren't rocket
science. Working out the solutions via complex quantities is good
learning for students (whether they like it or not); that CAN find a
need later in life when stuck with real design problems.

You haven't described your desired custom but memory says that
the 87 takes standard banana plugs connecting to the DVOM itself.
The socket on the meter has the extra insulation rim for a totally-
enclosed plugging in but the basic plug is still a banana plug that
has been around for decades.

Circuit-Specialists in Mesa, AZ, sells Fluke things and has a wide
assortment of Fluke test leads ranging from $11.50 to $37.50. You
can check them out at http://www.web-tronics.com.

They are quick on delivery over the Internet. I just got a bunch of
test equipment from them at my door only 4 days after placing the
order (UPS ground delivery).

Electronic Design is online at http://www.elecdesign.com

Their newer website makes it a bit difficult to search for Design
Ideas in past issues. Those probably don't go back farther than
2001 but I could be mistaken. Source code for those column
pieces requiring source is available as separate text files.

EDN is online at http://www.reed-electronics.com/ednmag

EDN's Design Ideas go back only to 1995...but are easier to
access.

>The synchronous detector used two analog multiplier chips and as I
>recall was contributed by someone with a callsign. Don't remember any
>other details. Anybody remember the magazine and the column?

I still get both Electronic Design and EDN, plus RF Design and
Microwaves & RF. Used to cut up the issues after a month or so

and file them for reference...until they all got on-line and I could write them onto a CD (much easier to reference, less space).

Don't recall the article or didn't bother to log it in memory as "important." :-) :-(

Motorola quit a whole bunch of specialty ICs a bit ago, very few showing up on other websites. They made a nice stereo AM IC that had an automatic synchronous detection system. Not enough market demand for it. ON Semiconductor still makes a few of the old Motorola line.

>Steve N, K,9;d, c. i My email has no u's.

Essentially, yes. There's a further step, though, and that is
locking a local mixing oscillator to the carrier frequency and
mixing that with the whole thing.

If the local mixing oscillator is in phase with the received
carrier, the mixing results in just a DC component which can
be removed easily. A carrier in-phase lock allows separate
detection of the sidebands...which could be used to
advantage such as having binaural audio modulation with AM.

That also works out well for a quasi-stereo listening with any
signal that is NOT binaurally modulated. The effect of hearing
through such a detector's audio cannot accurately be described
in words. Nearby-signal splatter can be "heard" as left or right
of the desired signal. Strange sound but does allow the mind's
own spatial filtering to sort-of blot out nearby interference.

That quasi-stereo circuit is a lot more complicated (it's usually
a typical Costas Loop with local mixing oscillator having shifts
for quadrature phasing) than the direct amplify-limit-clip-the-
bejeebers out of the carrier and mix that with whole works...as
was done in the Motorola MC1330P 8-pin DIP IC (now obsolete
but Kits&Parts as a few left).

>using a single sheet of metal and stamping machines?

Probably not. Commercial slot antennas are usually done with
waveguide for directivity and gain.

The Commercial Aviation section of RCA EASD in Van Nuys, CA,
was making X-Band aviation weather radar antennas using slotted
waveguide in 1975. It was lighter and more rugged with no loss of
beam pattern accuracy as compared to the old parabolic reflector
made of fiberglass-epoxy with a gold-plated mesh inlay. In order to
make it you would need aluminum dip-brazing techniques at your
disposal.

In going on down to 70 cm ham bands, a Yagi could be made with
a single-foil-layer PCB. That could be made weatherproof with an
overlay of substrate board epoxied in place. Yagi dimensions
would have to be altered for the denser medium of substrate dielectric,
but that could be determined empirically.

Slot antennas have been made for high-performance aircraft. Those
do not protrude into the airstream. However, the slot would still be
on the order of a half-wavelength long; the conducting part of the slot
antenna is the rim of the slot. No "high gain" there, only a "negative"
form of a folded dipole, pretty much the same RF characteristics.

Slot antennas have been around for about a half century in various
forms and flavors. Their chief advantage is a physical one for certain
applications. Information is in textbooks specializing on the shorter
wavelength antennas, very little quantitative info on the web.

Don't know about that particular instrument, but it might be
enlightening if you're not already aware, that the Smith chart is
simply a linear plot of the complex reflection coefficient, which is
pretty easy to get from an RF bridge. The chart overlays that linear
plot with the circular grid lines for resistance and reactance (and
conductance and admittance and various other things as desired).

Cheers,
Tom

Note that a sheet of metal hanging in on the wall with a horizontal
slot will radiate _vertical_ polarisation.

If a horizontal yagi would be replaced with a long sheet of metal with
slots where the yagi elements are replaced with slots, the
polarisation would be in the direction of the original yagi boom. You
might get some kind of broadside array radiating upwards if the
distance between the slots are suitable.

The autorouter should work. If you are thinking of using the autorouter
for your FSM don't bother, autorouters aren't much good for RF boards.
You will get much better results routing it manually.

>the defaults, and it routed the whole board in about ten seconds.

The "helpfile" says you can move the components to the board, position them, click on 'ratsnest' to get "airwires" to appear between the relevant nodes, then do the tools/auto bit and get the defaults you specify, then click "go" and the routing is automatically done. Unfortunately, however, no airwires appear, nor do any tracks. Nothing happens and the "helpfile" says autorouter isn't a working function in the Lite version! So far I can't say I'm exactly impressed...

>You _did_ create both a schematic, and a board layout, as part of the

This advice is good..... however.....

after many years of using the fluke 87, I have learnt that the plastic
shield also seems to help with a little mechanical support against the body
of the
meter.
Using the 4mm banana plugs works fine .....electrically....., but if
the leads are bumped frequently (which invaribably happens happens in an
industrial situation) , there is a fair chance that the extra leverage will
eventually cause the internal tube to break it's connection at the printed
circuit board, resulting in an intermittant connection there.
It is easy to check if this has happened, Just plug each end of a lead into
the "COM" and "V OHM" holes and with the meter on the ohms scale, wriggle
the plugs around, The bad connection wiill easliy be seen.

If you are handy with a screwdriver and a soldering iron this is easily
fixed (as I have frequently done)

Using the correct Shielded plugs seems to reduce the instance of this and I
am guessing that the little extra mechanical support
against the meter body is the reason for it.

But that's only my humble opinion.

> http://www.zoom-one.com

I really don't believe that a Fluke 87 connector is a banana plug. See
this site:

http://www.jensentools.com/product/group.asp?parent_id=8385

Like most modern multimeters, the Fluke 87 employs safety connectors
so that if a test lead pulls out of the meter, it doesn't pose a
safety hazard with an exposed conductor.

It is rare to see banana plugs used on many multimeters since the days
of the Simpson 260 and Triplett 630, and these were circa 1965. This
is because they were responsible for too many accidents. Today, banana
connectors are rarely seen other than insrumentation targeted at
accomplishing audio measurments, where it is commonplace.

Wish that I could provide information on the connectors that mate with
the Fluke 87, but without a search I have no idea what these
connectors are, or who makes them.

Even my cheap little Wavetek 5XL employs connectors of the shrouded
gendre, and while you probably can jam a banana plug into them (or a
twisted paper clip for that matter), you would negate the safety
features of the shrouded connector design and in some applications
their use would not only be unsafe but illegal.

Harry C.

I did do a version of that quasi-sync detector, using a Philips SA637 digital FM receiver chip. I took one of the limiter outputs and fed it back into the LO input of the on-board mixer. The 455kHz I.F. signal was applied to the RF input of the on-board mixer, and the audio was taken from the I.F. output of this mixer. Not bad, although the demodulated audio level was fairly low (about 50mV p-p). I was actually considering using that detector, until I discovered the appnote for the Analog Devices AD607.

Hi Dave
I find it works better if you don't run power through the short.
I run the supply along one of the traces. I then place one lead
of the DVM on the trace that it is shorted to. I run the other lead
along the trace with the power supply and look for a null. This method,
with a slight variation even works for power plane shorts. I go from
opposite corners and lay a piece of string along the null lines.
Where they cross is where the short is.

Of course, what we've tended to see is an all or nothing thing when it comes to AM (with carrier) detection. A simple diode detector, or a PLL based synchronous detector (with or without phasing for sideband selection). In some ways, it's been driven by market not by curiosity. In the early seventies, those Signetic 56X series of analog PLLs came along, and simple synchronous detectors (or outright receivers) were all over the place. Most of the people applying them in hobby circles hadn't woke up one day and said "we need a better AM detector", it was because all of a sudden one could get the function on a single IC. So there was a novelty, if nothing else. Various communication type ICs came along at that point, and people were interested in "all mode" detectors from them. Since a double balanced mixer was common to most of such ICs (the MC1496, various FM detectors, the LM373, various Plessey ICs and let's not forget Ralph Burhan making a Loran C receiver out of an IC made for simple AM/FM broadcast reception), it certainly caused an interest in simple quasi-synchronous or outright synchronous detectors. But again, it often seemed to be "how can we get the most out of this IC" rather than "let's try to improve the lowly AM detector".

So there have been very little instances of biased diode detectors (I think one of the Drake receivers used one, and Rohde showed a few in his Ham Radio articles a quarter century ago, and I've seen some in Wireless World in years gone by). Whether or not that is a useful path, there never was the level of interest in trying such things that there was for synchronous detectors, even before the latter became easy with ICs.

And while at one point the limiter feeding the product detector was described as a "synchronous detector" and worthy of experimentation, as fancier detectors became more common, they are dismissed as merely quasi-synchronous and maybe not even worth the effort. Yet, they are a middle ground, maybe offering some increase in performance without the extra circuitry of a PLL based detector. I can point

to a 1955 (I think) article in QST where someone built a fancy
receiver, with two parallel IF strips. One was AM bandwidth,
the other CW bandwidth. But, there was switching at the outputs
of the IF strips, so the CW strip could feed the product detector
at the output of the voice IF, and get some level of increased performance.

Let's not forget (to the original poster) that the whole point
of going beyond a diode detector is to improve operation with weak
carriers compared to the sidebands, or for that matter with adjacent
channel interference. The synchronous comes about because one needs
the reinserted carrier right where the incoming carrier is, but
except for that need, it's all about mixing the incoming signal down
to audio, just as in sideband reception. With a strong signal, the diode
mixer works fine for that, mixing the sidebands with the carrier. But as
the carrier weakens, or an adjacent signal becomes stronger to "capture"
the detector, the simple diode detector suffers.

Long before before CQ ran the article about the synchronous detector
in 1958 or so, most or all hams who tried for better AM reception tried
other things. Like boosting the carrier of an incoming signal in
reference to the sidebands, "exalted carrier". The common, or maybe
only means, of doing this was by using a Q-Multiplier, which could
provide a narrow peak for the carrier, but a relatively sloppy
skit so it didn't attenuate the sidebands too much. Nobody talks
about this anymore, even though we've seen in this thread the comment
"simple and good" don't apply to synchronous detectors. But how
much improvement is needed, versus how much circuitry one is willing
to accept?

The subject line pretty much says it.

Need HP/Agilent 346A or 346B noise source with BNC connector
on bias end and N connector on output end.

Must be in good condition and fully functional - no burn-outs, please.

If you have one/know where I can find a reasonable deal on one,
please contact me by direct e-mail at wk3c@wk3c.com please.
(note, the e-mail address in the line above is on a different machine
than I use for usenet, please reply there for prompt attention)

73,
Carl - wk3c

I'll have to disagree there. A year ago I got an excellent 4 1/2 digit precision DVOM+freq-meter+other things and it had the insulated test lead bananas. Made in France, sold by Mouser. Last week I got some test equipment from Circuit Specialists, enough that they included a free promotional-item DVOM. It too had the shrouded banana plug test lead connections to the DVOM. Normal retail about $39, made in China.

I've used "exposed" banana plug connectors (usually made by Pomona) for the last forty-plus years for many things, including plate supply connecting leads. Not even a tickle from B+ of 300 VDC. It all depends on how the individual handles things and there is no guarantee of not goofing up with the most shrouded of test lead constructions.

>Wish that I could provide information on the connectors that mate with
>the Fluke 87, but without a search I have no idea what these
>connectors are, or who makes them.

Try the Fluke site directly or the link I provided for Circuit Specialists (web-tronics.com), going to the Fluke button. Fluke name on all the various test lead thingies under that button...lots of combinations.

>Even my cheap little Wavetek 5XL employs connectors of the shrouded

With the terribly high voltages of today's circuitry (30 VDC), I don't think many are going to off themselves even by grabbing the metal of banana plugs instead of the insulated body.

If in doubt, wear linesman's gloves. :-)

Over the last few years I've acquired quite a few consumer electronincs pcbs including TVs, VCRs, stereos, etc, so when I discovered that I needed a tantalum to repair some test equipment I was going to salvage a tantalum. I couldn't find one anywhere, so I assume they're too expensive or too unrelaible for high end consumer electronics. A couple of the boards were from my personal stuff purchased new. One example is a MGA Mitsubishi rear projection TV that operated flawlessly for nearly 20 years of daily use. Most of my test equipment comes from hamfests and is surplus after becoming obsolete and non-operative in less than 20 years. That leads me to wonder what the real story is behind tantalum capacitors. What do the experts have to say?

They can have very good characteristics (small size, low esr, high
parallel resistance and good capacitance stability) but have some
strange failure modes if they are misapplied. Digikey sells a great
variety of them. I can seldom justify their cost in production
designs, but use them quite often in one offs.

Modern aluminum can have very low esr and an adequate alternative to
tantalum.

So in a production design, what would you use to get the equivalent
performance? An aluminum electrolytic in parallel with a ceramic?

We often use surface-mount tantalums on high-density, high-cost
boards. They are very reliable (don't dry out like aluminums) if used
carefully, but high peak currents can ignite them, so they are
generally a bad idea for bypassing power rails.

Polymer aluminums (don't dry out) or polymer tantalums (don't explode)
seem like a good idea, but I haven't tried them yet.

I think multilayer ceramics are pushing 100 uF these days.

John

A production design usually pays for the engineering necessary to
reduce the need for premium quality components. Your solution is
often a cheaper alternative to a premium quality tantalum.

I have a Racal 9301A where a tantalum must have caught on fire because all
that was left was 2 leads, some crisp blackish ash and a little hardened
crust on the pcb where it burned. There's probaby 10 other tants on the
board and one or more are shorted but still intact and I'm trying to find
the bads one/ones with least effort without a schematic. The other unit is
a Wavetek 188-S1257 where a tantalum had a dead short but was intact. I
repalced it with an electrolytic. The cap is on a 15 volt rail where I
think it shorted and took out the regulator. Ireplace the regulator with
what I assumed was a good one out of a new box but it was bad and it put 23
volts on the rail that had a 20 volt rating but no more failed. Sometime I
have good luck.

Consumer electronics are costed down to the lowest possible level. If
they can use something cheaper, they WILL use something cheaper. A TV
set or VCR has had people go over the design hundreds of times with
BOMs and catalogs, checking to see if they can shave a penny here or a
penny there.

Computer equipment is a good source for tantalums - motherboards, hard
drive PCBAs, etc. Of course, it will be surface-mount :)

Tantalum capacitors became a component item about 45 (or so) years
ago and originally favored in spacecraft and aircraft because they could
contain lots of electrostatic storage in a small space with ligher weight.
That was when PCBs were relatively new, quite new in spacecraft
electronics.

It hasn't been until the last decade or so that the cost of tantalum
capacitors has approached the level of improved electrolytic
capacitors of the same value. Tantalums are still relatively
expensive but they are good for SMT due to their smaller size;
its a trade-off between cost and overall system size in that case.

Inherent problems in tanatalum capacitors have been improved
since their initial debut as a component but so have electrolytic
capacitors and their manufacturing methods. One can purchase
FARAD-value low-voltage electrolytics now where once it was
not possible unless one had a room to put them in.

I was just looking at my 2002 handbook, and there was a circuit for a synchronous detector, in the receiver chapter. It wasn't "simple", but it was there. It also uses NE604s (the companion chip to the '602), which might not be available any more.

I wouldn't assume that just because your test equipment comes to you broken is a result of tantalum caps -- perhaps your sample is skewed by buying at hamfests instead of burgling active technology companies? Maybe if you only acquired your home entertainment equipment from dumpsters you'd conclude that aluminum electrolytics are bad?

I recently escaped from a company that does aero (but not space) systems. They get mounted on aircraft and are expected to survive being shipped in an unpressurized cargo hold at 50000 feet. At that altitude a wet aluminum electrolytic will dry out, but a tantalum will be fine. There are even wet-slug tantalums for high-altitude applications that will not dry out at these altitudes.

The problems with tantalum are their fragility (we've had exploding caps on our boards, with one manufacturer's part being fine and another being horrid), cost, and the relative scarcity of tantalum. Does anyone remember the Great Tantalum Shortage of a couple of years ago? One of the big tantalum supplying regions is central Africa, and a combination of wars reducing supply and increased demand led to some supply problems for a while -- I remember that at least one of the manufacturers even came out with a Niobium cap as a substitute.

Hi all,
tantalum caps seem to be too expensive for consumer-grade equipment.
They contain pricey material - silver and, of course, tantalum, so
making them cheaper is impossible. AFAIK they are widely used in
military-grade equipment, where the price is not an issue. Their main
advantages are a longer life (they do not dry out nor leak) and a
bigger temperature range (frost resistance).
About using cheap parts in consumer electronics: At least 80 percent
of failures of certain types of TV sets were caused by dried-out
aluminum caps. The good practice when repairing these sets was: first
check all electrolyte caps by adding a good one in parralel. It was
successful very often.

Yes, but alas, only with zero volts across them. Capacitance
drops precipitously with DC bias. For a cap with Y5V dielectric,
at half the rated DC voltage, there's only 10% of the initial
capacitance left. Most manufacturers don't tell you.

It is important to use the "net" icon/command and not "wire" on the schematic to connect your signals.

I didn't think it was quite as bad as that. Also very temperature
dependent. These type of ceramics are also pyroelectric as well as being
piezoelectric!

Which opens up the possibility of using them as parametric amplifiers
or modulators. I have a paper somewhere that uses the nonlinearity of
ceramic caps to make a nonlinear transmission line - a shock line -
that sharpens the rising edge speed of kilovolt pulses.

Wet-slug tants are expensive (do they still have silver cases?) but
don't blow up like the dry ones. The dry slugs coat the sintered
tantalum (fuel) with MnO2 (oxidizer).

This is really erratic. One spool of tants will be bombs, another
can't be made to fail by deliberate abuse.

> to say?

The ONLY problems I've ever had with tantalums are where:

(1) The part was defective from the manufacturer.

(2) The voltage rating was consistently exceeded.

(3) The thing was installed backwards (reverse polarity).

I have no less than five Tektronix O-scopes here, all vintage
late-70's to mid-80's. This means not one of them is less than 20 years
old. They all use lots of tantalums, and they all work great, but then
again Tek was (in those days) proud of what they put out, and was most
definitely engineer-driven (which means at least a 20% 'fudge factor'
built into everything they made).

Tantalum caps are very stable and durable, but they are much more
costly than aluminum types. In consumer electronics, the manufacturers
will try to shave every penny they can off the cost of the design, often
contrary to good common (engineering) sense.

Such considerations are (usually) not so critical when it comes to
non-consumer stuff.

Keep the peace(es).

Boy are they ever. I have some surplus ones, but they have cases that are
more of a silver-gray than that nice yellowish-white look you get from
silver-plated connectors. These are special parts, but if you want a
generally high-performance cap in a (relatively) small package they're hard
to beat.

I worked for a while on a project to make a power-wire networking device.
During testing I accidentally dragged a scope ground across a circuit that
was referenced to the 115V power line, thereby exceeding the tantalum cap's
voltage rating -- er -- "slightly". Little pieces of flaming capacitors
bounced around the lab. After that all of my digital logic (3.3V and lower)
coworkers _never_ messed with my bench.

Interesting. I'll have to remember that. Thanks. In any case when
designing with _any_ electrolytic capacitor it's best to use specify a cap
for 20-50% higher voltage than what you think it's ever going to see,
particularly because many voltage regulators overshoot on power up and the
output cap sees more voltage than you think.

Silver cased wet slug tantalums DO explode, most contracts that
allow the use of wet slugs require the use of tantalum cased parts.

Tektronix was, during that time, strongly discouraging all new designs from
using tantalums. IIRC they had been taken to court over a case in which
a 465 'scope (the original, not the plastic follow-ons) had spontaneously
ignited and had resulted in an expensive fire. Forensics revealed that
a tantalum power-supply bypass cap had started the conflagration. The
drive to reduce tantalum usage was driven primarily by this liability issue,

more than component cost. If you wanted to use a tantalum, you had to justify its usage to the component/design review committees -- which wasn't difficult if you had good reasons and your design was solid.

Some years ago I wandered into one of the design labs to ask some questions about a new thingy we were doing.

On a bench was a metal trash can with wires leading to a power supply, thermometer, and a chart recorder.

"What's all this", I ask.

"Getting some real data on stressing tantalums. The trash can is a blast shield just in case" was the answer.

Just after the guy running the test uttered the words "looks like nothing bad is going to happen" the cap exploded with the trash can acting as a megaphone for the bang and director for the shrapnel; everyone around hit the deck.

We got off the floor and looked up to the acoustical ceiling where there was capacitor pieces and an alligator clip embedded therein.

When the guy running the test said "Maybe we had better rethink this design", I decided to go back to my lab and come back on a better day.

We continued to use tantalums (aerospace), but there were a lot more explosions in the lab to make sure they didn't happen on the shipped product.

As someone who had a big (non-Tantalum) filter cap explode _right_
next to my one-and-only, precious, irreplaceable face, I approve
of this strategy. It sure as blazes beats having a cap in the power
supply drawer imbed itself in the ceiling, missing a cheekbone by
about 1/4", and it also beats having to go through hundreds of power
supplies in the comm center, looking for bulging caps.

We found -- and replaced -- about a thousand. I'm still pretty antsy
about working on anything with filter caps in it, and tend to put a
straight-edge along the can to see if it's bulging. If it _is_, I
just replace it.

Read the data books carefully. There is a formulae relating source
resistance, proof voltage/actual voltage and capacitance.
Note early Plessey button tantalum (very reliable) incorporated liquid
conc nitric? dont blow them up!

I've seen more than one problem with high-value ceramics causing problems during operational vibe tests because of microphonics. In our case it usually seems to be the vibration causing capacitance change rather than true piezoelectricity, but it happens in any case. The last one that I remember we replaced the ceramic caps with back-to-back tantalums, in fact. Worked like a charm.

Epidemic faults were, in my experience, rarely caused by cost-reduction
but either by component manufacturing faults (noisy tantalum caps and
unreliable fuses, for example) or by unrecognized 'gotchas' in the
original circuits (high-Q series resonance in a loudspeaker crossover
filter).

>They contain pricey material - silver and, of course, tantalum,

No. We used quite a lot of tantalum 'bead' caps in consumer audio and TV
until we found the problems they have and we could get aluminium
electrolytics 'with no added salt', so they didn't leak and were much
more reliable. I still have some boards with them fitted.

The problem with Al caps drying out is mainly that people let them get
too hot. They were rated at 75 C or 85 C *max. ambient*, not
'temperature rise'. It's still a problem; we have 'designer' set-top
boxes with no ventilation, and service people put 130 C rated Al caps in
them as replacements; 105 C rated is often not good enough!

Wow! I didn't know this... Thanks for the neat bit of history.

I will add that most of the tantalums I'm finding in my gear are
localized filters for the power-input traces in 7000-series O-scope
plug-ins.

Everything still works great, though. ;-)

I was there at the time, too. Tantalums were essentially verboten unless the source impedance supplying the tantalum cap was at least 3 ohms/volt. That's because it was found that the short circuit failure mode was aggravated by high inrush current, so the source current had to be limited. One of the chief reasons we had been using tantalums in the first place is that they have very good bypass characteristics up to quite high frequencies -- so a single capacitor could handle a very wide range. When the source impedance was high, the capacitor didn't need to be so good in the first place, and of course adding a physical resistor in series with a supply bypass pretty much defeats the whole purpose. Consequently, the 3 ohms/volt rule pretty much eliminated tantalums as a viable choice for most applications. Fortunately, it was at just about the same time that very big improvements were made in aluminum capacitor technology. As the aluminums shrunk in size, they became much better at bypassing higher frequencies. So they took over from tantalums pretty rapidly. There was a glitch for a while, though -- boards were being cleaned with Freon at the time, and it was discovered that Freon could migrate past the seals on some or most aluminum capacitors and corrode the aluminum, leading to poor reliability. The solution adoped by some manufacturers was to add a rubber seal at the lead end of the capacitor. That increased the length of the leads between the outside of the capacitor and the inner body, increasing the lead inductance and decreasing the capacitor's high frequency bypass capability. . . but that's just another example of the day-to-day problems an engineer faces and has to overcome.

Incidentally, I got a Tek 1502 TDR on eBay not long ago. It had a shorted tanalum power supply bypass capacitor.

A couple of other anecdotes -- A time base plugin I designed had gotten through the entire extensive pre-production test phases, accelerated life tests, etc., and was in pilot production. I walked past the production line technician's bench every day, and began noticing several tantalum capacitors of the same type in the replaced-component box. They had come from a sweep circuit I had essentially copied from an instrument which had been in production for some time. Puzzled, I analyzed the circuit carefully, and discovered that at an extreme setting of one control, the tantalum cap could have a very small reverse voltage applied. I modified the circuit to eliminate the possibility of any reverse voltage of any level, and the capacitors quit failing. Servicing data from the instrument I had copied the circuit from showed noticeably reduced reliability of the capacitor, also. The lesson learned is that tantalums won't tolerate _any_ reverse voltage. If they don't fail immediately, a disproportionate number will fail eventually.

The other anecdote involves a QRP rig. As a crude reverse-voltage protection, I had reverse-connected a 3-watt diode (actually, a 36 volt zener I had lots of) across the power supply terminals. My battery supply normally had an-line fuse which would blow. Just before Field Day one year, the fuse holder broke and I didn't have a spare in the junk box. I'd never blown a fuse in 20 years of Field Days, so went without. The battery was a 12 volt, 5 Ah sealed lead acid unit, capable of a few hundred amps if shorted. As I'm sure you've guessed, that was to be The Year of the Reverse Connected Supply. The wires to the battery immediately melted out of their insulation, burning some holes in the tent floor. I managed to disconnect the battery without getting burned and before a real fire started, and checked the damage. The rig's (recently installed) power switch was fortunately off, so the innards didn't get any reverse voltage. The diode had gotten so hot that the plastic case had fractured and probably burned -- it was gone. The diode's solder joints had melted, and the two separated diode leads were dangling. But there was still a dead short across the terminals -- a small 6.8 uF dipped tantalum capacitor was also across the terminals, and it had become such a good short that it hadn't gotten hot enough to explode. (The power supply wires were something like #24 or #26, so they'd limited the current.) My guess is that it went short just as soon as the diode opened, and made a better quality short than the diode had. The fuse is now back in place (along with new diode and capacitor), so of course I haven't reverse connected the supply since.

"Costing down" does not mean "making inappropriate component
substitutions", and I wasn't suggesting or advocating such a policy.
It means, quite simply, going over the circuit and seeing where a
cheaper design or a cheaper, _compatible_ substitute can be used. If
the device has a 12 month warranty, and it dies after that period
expires, then nobody really cares which component was the first to
fail. Especially in disposable consumer electronics!

As I recall, it was a couple of tenths of a volt. The capacitor was probably a 12 or 25 volt unit.

A quick scan of the web shows that some manufacturers claim their tantalum capacitors will withstand something like 10% of rated voltage (not to exceed 1 volt) at 25 degrees C, and 3 - 5% of rated voltage (not to exceed 0.5 volt) at 85 degrees C, with a time limit on application of reverse voltage. Because of my experience, though, I'd consider it to be bad design practice to allow any reverse voltage at all until I saw some reliability figures for capacitors used under those conditions. The problem is that it doesn't cause immediate failure, or even assured failure -- it just increases the probability of failure. Some applications can tolerate the increased failure rate, and some can't. At Tek, a great deal of importance was placed on reliability.

Few years ago, my boss came in, laid a printed schematic on my desk, and
said "Put this in PSpice, so we can demo it to a customer. I said OK,
and started entering the design. He comes in a couple of hours later,
and wants to know if it is finished! I go, SaWha? He now tells me that

he is getting on a plane in a few hours, and has a meeting with the customer in the morning! So I get to it, end up emailing it to him the next morning, as there were some digital parts not in the standard libraries, had several components that I had to create, etc. There are still major bugs in the simulation, etc. That afternoon, he calls, and says that they were mad because they didn't see what they were looking for in the simulation. I ask, What were they looking for? And he tells me, this cap in the power supply keeps exploding! I then realize he is talking about the tantalum! Since I had just seen a thread like this one, I knew about tantalums, so I told him that there was no way we were going to create a special model for PSpice for tantalum caps! Most designers just knew not to use them as power supply filters!

Got a bad review from him that year. I now know that, when you get an assignment, ask LOTS of questions, to the actual customer whenever possible! 8-)

Didn't see anyone else mention that aluminum electrolytics don't work
well when cold, but tantalums keep working fine.

Your test equipment probably became "obsolete" because the things
being tested were newer and more sophisticated than the equipment was
designed for, and therefore it was no longer needed. Technology moves
along rather swiftly these days. If all analog TV signals were
discontinued with only digital available, your old rear projection TV
would also be obsolete. Test equipment is commonly much more
sophisticated than consumer...drifts that are practically unnoticable
in consumer electronics would be intolerable in test equipment. But
even so, I have plenty of test equipment that's 20+ years old that
still works fine. I've had to repair (or toss) a higher percentage of
my consumer electronics than of my test equipment, for sure.
"Discman" type CD players seem to have an especially short life, but
I've had tape recorders, TVs and at least one stereo amplifier fail as
well.

Cheers,
Tom

no, not really, I suffered the same information problems, but - you
know - most such devices are almost equal, so if you have an old
Motorola, RCA or Philips data book and look at the connections in an
application you can extract a lot of info and don't need to have exact
info. Often the gain is higher, so when the manufacturer says it needs
100mV it may sometimes work perfectly well on 10mW, and when they say
that Vc1 and Vc2 should be 12V, you may even key Vc1 or put a
potmeter in series to adjust the output, but electrolytics on the
supply voltages seem important to avoid spurious

Hi gang,
Does anyone remember a product from the late 60's or early 70's called "Norelco Electronics Lab"? It was a lot like the current "100 in one" electronic sets, but on a more sophisticated level. Seems to me it had some early Ge transistors in it.

Thanks

Bob WB0POQ

Sure, any cap will explode if you dump enough energy into it. The
difference is that the dry Ta:MnO2 guys only need a tiny bit of energy
to ignite, then chemically explode on their own. Just a high dV/dT
```

will set one off.

Did it have a bunch of little sugar-cube sized pieces, with four- or five-contact gizmos that you stuck wire into for each componant lead (like a single-row proto board)? You stuck the pieces down on a board and wired them together. I had a bachelor uncle who was an EE, and I always pestered him for electronics stuff for Christmas. One year he gave me such a beast. I remember really liking it, but it must not have lasted very long, because I sure don't have it now!

Most CRT monitors radiate enough noise to raise the noise floor to an
unacceptable level. One of the best remedies is to use good quality coax and
to keep the antenna as far away from the monitor as possible.

No, I don't think so. As I recall it had regular components that were connected between spring loaded posts. I think it had a schematic sheet that you laid down on a board like pegboard, put the posts in and then added the components.

I remember a similar product here in the UK called the Philips Electronic Engineer Kit. I had hours of fun with it in the early '70's. The only transistors I remember were BC548's mounted on small PCBs which depressed the spring contacts and were held in place when other components were added.

But now I try to remember which transistors they were, I not so sure about the BC548 bit. Childhood memories can be very unreliable!

Hi

I think they were AC126 (audio) and AF116 (HF) germanium transistors.

I vaguely remember it. Norelco is a Philips trade name, it seems to be
used now for their shavers in the US. It probably used Mullard devices
(Mullard was taken over by Philips).

==========
From Mainline Electronics -Leicester /Mitsubishi catalogue here it goes :
M57741UL 135-148 MHz ,Po=28W, Gp=21.4dB, Pin=200mW, Vcc=12.5V, Pin=3.3 ?
M57741L 148-160 MHz , 30 ditto
M57741M 156-168 MHz , 28 ditto

Don't know what Pin (no dimension) =3.3 means ,perhaps idle power without
input signal.
Since Vbb is not specified a note says that the power modules are NOT
suitable for SSB operation .
Package outline code : H2 ,showing dimensions and 4 wire connections (no
connection designations included)

For max. Vcc=17 V ,Pout is 35W
However personal experience with this range of power modules is that to
ensure reliable long term operation it is better to operate them below their
rated specs.
Example: A 25 W module used in a 2m Packet Radio BBS transceiver (FM) which
operates on a 24/7 basis has been set for 10 W operation. This is 4dB down
or just over half an S-point on rx.

How do I eliminate noise from a pc monitor?

I solved my problem by changing the monitor color display from 256 to 16. This cut the noise right out.

After looking for a real easy and uncomplicated solution, with pc and tcvr on, I rebooted the pc in dos mode and when the b&w screen appeared there was no noise from monitor.

Then I went to control panel, found the display info and changed the color to 16.
For some reason, too many colors create noise. (Why?)

Thanks to all for your help.

Less colors use a simpler drive signal to the CRT. Also, selecting a
different video resolution will move the sweep frequency.

581. Tantalums and test eqpt.

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-23 15:22:38 UTC
From: Henry Kolesnik <wd5jfr@oklahoma.net>
Message-ID: <1012f225l61me6e@corp.supernews.com>
Source record: 29168

I like good test equipment and when I started in the 1950s good was homebrew, war surplus and the local radio TV shop. Then in the RCAF it was a Tek 545 and later at university it was a Tek 545B. (I worked my way thru college as a TV repairman working 20 to 30 hrs per week!) After university and when I had spare cash I graduated from homebrew and surplus to kits. Then my first good bad scope was an HP 120. Nothing but problems with the HV supply. Now unwllingly retired at 63 one of my passions is to build a up a small lab for personal enjoyment by finding at good prices test equipment made by the best mfgs such as Tektronix , GR, HP, Fluke, Boonton, and others, but the others usually don't hold a candle to the top 4. Others include Wavetek, Racal, Philips, Systron Donner, etc. There's a third class that includes Heathkit, Eico, RCA, Sencore, B&K and others who furnish radio and TV test bench eqpt and I have some that is very, very good. A fourth class is foreign like Marconi, Meguro, Siemens, Rohde & Schwarz, all excellent but that I generally shy away from them because information and parts are in the unobtanium category.
Generally finding a very good deal at a swapmeet means there's something wrong with it, either unknown or undisclosed by the previous owner. Finding docs for the best is hard enough but an order of magnitude harder for the others and that goes another order of mag for parts. Sometimes one needs 2 or 3 junkers to succeed or give up.
I don't like to leave a swapmeet without some good deal that I can take home and plug into the Variac to see what it does. Generally I'll look inside to see if it's complete with no obvious missing parts and no char babies. Then I turn the Variac up and watch the current and look and smell to see if all the smoke the the factory sealed-in is still there. If it is but it doesn't work I check power supply voltages. It never ceases to amaze me that very few of the mfgs have figured out how to build a reliable power supply. In my work, Telecom, most critical hicap stuff had dual supplies so it could still operate if one supply failed and to top that off they migrated to hot swapable supplies! My own theory on power supply unreliability is that the companies assign newly graduated engineers to design power supplies and those guys don't have enough experience to understand the ravages of long term heat, continual cycling and the crazy stuff that can come down the AC power line! One exception today may be PC power supplies as I don't see boatloads at the meets like I used to but maybe it's because I'm not looking!
First, I check the supply voltages and if they're down I check the rectifiers and capacitors. Many times I'm lucky and find the problem right away but other times if its a short it a arduos process on pcb. After much wasted time the bad cap is found, an Al electrolytic if there are no or few tantalums but if there's lot of tants there's a very good chance it's one of the tantalums with a dead short and not exploded. Partial short are best because they make char babies!

If the fault isn't in the power supply or on a supply rail it soon
becomes a waste of time without a manual.
To end this mild diatribe, obsolescence of test eqpt is a matter of
economics for business and sadly me! I still like my Boonton 260 Q meter but
I'd rather have an HP 4342A and I'd rather have an HP 8921A to replace my HP
141T, a newer Tektronix TDS to replace my Tek 465. Space, time, dollars,
and performance all suffer in my lab but it's there for my enjoyment and
entertainment. and most likely to be upgraded with smaller, higher
performing, newer, less obsolete gadgets.

I got some from Bardwells that were about 20mm dia and when
close-wound all round with one layer of 0.7mm enamel wire came out at
exactly 1mH (which was handy since that was the objective!). Give them
a try. They do mail order and are very reasonable.

Don't count your chickens before they hatch. Haste makes waste. Sometimes "simple" solutions don't work.

Info on an earlier post today proclaims my solution. Not so :-(Changing color display to 16 merely cut the noise on one frequency, and the noise appears on a couple of different frequencies.

Therefore, before I post solutions - like a good scientist - I will carefully observe and test and re-test.

There are two basic categories of toroid cores. Those that contain distributed gaps between bits or sections of high permeability material (to increase their energy storage capability) and those made with a single material that has a high permeability (may be metal, metal tape or ferrite ceramic).

The T series are the distributed gap type. Their claim to fame is their ability to have stable inductance with high ampere turns applied. So before you can choose a core material, you not only have to specify the inductance required, but the ampere turns this inductance must support.

Here are links to a few ferrite manufacturers:
http://www.fair-rite.com/
http://www.mag-inc.com/ (also makes the powdered iron cores)
http://www.neosid.com/fercor/toroids/tormn.htm
http://www.ferroxcube.com/prod/assets/fertor.htm
http://tciceramics.com/f_toroid.htm

Many others are available through Google. The first link includes an inductor design tutorial at the back of their catalog that may be helpful.

587. How good is ferrite 75 material for crystal AM radio?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-23 17:29:43 UTC
From: beginner <beginner@nowhere.com>
Message-ID: <1012mg7devgth5c@corp.supernews.com>
Source record: 29174

I made an inductor by winding 14 turns on T82-75 torroid.
Using 180 pF variable capacitor, in a crystal radio circuit I could not pick up any signal but even with a 470 uH modded inductor I picked up a few signals.

Is this material not suitable for this appication?

Thanks

Many companies view power supply design as unchallenging, and many engineers see it as boring. So power supply design often gets relegated to dull people or new grads. There is a grain of truth there, in that power supply design is a lot about remembering all the ways that previous designs have failed and not doing that again, and not so much about applying the latest technology that's coming down the pike.

The two best power supplier designers that I can bring to mind are (one) a guy who never did get his BS in EE, but designed power supplies for decades and could tell you every possible way that one could fail and what to do about it, and (two) a guy who usually does video design, but only because he does _everything_ right -- and when he does a power supply or is the technical lead over someone doing a power supply it always works. Both of these guys are technically paranoid and have long memories, which is really what it takes.

I am not familiar with this core number, but if it is actually made of
Fair-Rite type 75 ferrite, it is not very good for making 1 MHz
inductors. It is low resistivity (acts as a loaded turn in parallel
with your inductance) and quite a bit of hysterisis loss. Are you
sure it is ferrite? Can you measure the contact resistance between
two points on the core with your ohm meter?

Whatever the material, a core shape is not well suited to pickup fields.

Instead, use an opened one, like ferrite sticks. Unfortunately you'll have
to have many more turns.

Fred.

I had something like that, but IIRC it was called "Electro" the components were enclosed in small plastic cubes (about 1 inch) with clear sides and white tops with the schematic symbol printed on them. The cubes had flat metal plates on the sides and a magnet on the bottom to hold them to a metal ground plane plate.

To build projects all you needed to do, was copy the schematic in the book by lining up the cubes on the metal ground board.

If you have a good antenna do you _want_ to use a coil that's going to pick up fields? I would think you'd want to control the energy getting into your set.

What ever happened to buying a bottle of fancy whiskey and using the cardboard tube it came in for a coil?

I constructed and tested that circuit with a Yaesu FRG-100. It works
reasonably well for ground wave signals. However, it has problems
staying locked during carrier fades. I tinkered extensively with the
phase lock gain and time constants, but to little avail.

The audio quality for local MW stations was amazingly good, however...

>please help? Thank you very much.~~Ray

On pages 75-76 of 73 Magazine for some month ending in "ER" in 1971
(I can't be more specific; years ago I tore the article from
the magazine and punched holes so I could put it in a three-ring
binder. The bottom hole wipped out the rest of the month name!)
is an article "Converting the AC/DC for WWV" by John S. Hollar, Jr.,
W3JJU. The "AC/DC" was also known as an "All American Five".

In the article, Mr. Hollar described how he rebuilt the converter
circuit to receive WWV at 10MHz; he said it worked fine in Pennsylvania,
even during daylight hours.

Just about any shortwave radio that covers 5, 10, 15, and 20 MHz will easily
pickup WWV. You can find relativily cheap transistor ones that will serve
the purpose and save you lots of time and perhpas money.

Ray,
Assuming that your emphasis is on building rather than buying,
you can do a google search for "shortwave receiver schematic" which yields
numerous choices including this very simple one:
http://braincambre500.freeservers.com/shortwave%20receiver.htm

my conclusion worth a penny is that it depends on whether you are
building a transformer or inductor, in the first place the core you
refer to may be good for a transformer, but suppose it is useless for
most applications as an inductor

Yes it is definitely a core T82-75 from the labeling on the package.
Which parameter specifies that it has low resistivity?
Can this be used as a transmission line transformer of a balanced mixer?

Which ferrite material works well for the AM band around 1 MHz?

I can get core #43, 61, and 63.

Thanks for the input folks.

I'm needing to make several attenuator strips but I don't have much in the way of precision
resistors... I do however have a boatload of FT-37-43 toroids!

In "Solid State Design for the Radio Amateur", there is a schematic for making a 20-db
directional coupler for the purpose of attenuation. My question to the group is how
to cascade the couplers as an attenuator strip, and what type of resistive termination
I am likely to need.

I can't assume that either the source or load of the strip will be 50-ohms, so I wonder if
I need to place a 50 ohm resistor between couplers, and whether I the connection needs
to be series or shunt?

Thanks in advance,

The Eternal Squire

I wouldn't use ferrite at all for this application. A suitable iron
powder core would be a lot better:

http://www.amidoncorp.com/aai_ironpowdercores.htm

One of the #15 material cores would be ideal.

Well, the truck is going in to Ford this coming week. Needs the CD player replaced and they will install the filter in the fuel tank at no charge, so I might as well have it done. Is anybody aware of any other tech service bulletins for noise? My Ford dealer says if there is a TSB, they will do it as warranty work at no charge. Sure would like to load up on all the RFI bulletins while it's still in warranty!

==========
Am I getting confused ? I thought the designation T82-75 identifies a
powder iron toroid , having a 0.82 inch outer diameter and is made of 75
type (mix)of material.
If ferrite it would be labelled FT82-75.

In my file I keep a snippet from QST ? in which Zack Lau (ARRL Lab)
highlights identification of Ferrite type of materials as follows:
Quote ----------

You may be able to grade your ferrites by resistivity. Just stick an
Ohmmeter across or bead in question and measure its resistance.
The readings you'll may not be narrowly definitive ,but if your parts
collection contains toroids of only a few types ,you may be able to separate
one mix from another according to Table 2.

Table 2
Typical Resistances of Small Ferrite Beads/Toroids

Material / Resistance
43 10 MOhm
61 > 30 MOhm
63 > 30 MOhm
64 > 30 MOhm
72 > 30 MOhm
73 20 KOhm to 100KOhm
75 5 KOhm to 20KOhm

Note by WJ1Z : It's a good idea to color-code your ferrite materials as you
require them (example : mix 43= red , mix61 =blue ,
mix 75 = green . When your cores arrive ,segregate them by mix and working
with each type in turn ,spread each lot on a sheet of newsprint and

spray-paint them (one face will will do) according to your color code .
Be sure to record and save the key !

Unquote ----------

From the above table it shows that with its relatively low resistivity ,mix
75 contains relatively much iron ,which indicates the material is suitable
for low frequencies only , perhaps even not RF.

The OP said it was ferrite. Assuming he is referring to an Amidon
product 75 is a ferrite mix:

MATERIAL ' J '/75 (ï¿½ = 5000) Low volume resistivity and low core loss
from 1 KHZ to 1MHz. Used for pulse transformers and low level wide band
transformers. Excellent frequency attenuation from 0.5 MHZ to 20 MHz.
Available in toroidal form and ferrite beads as standard off the shelf
in stock. Also available in pot cores, RM cores, E & U cores as custom
ordered parts with lead time for delivery.

I'd say this was quite unsuitable for his purpose. It would be OK for a
wide-band transformer, as he suggests.

It depends on the frequency (you need to make sure that the correct core
is used), the core and the size.

As long as you're talking about an inductor or a transformer operating
at the same frequency, I think any core material that works well for
one will work well for the other.

What the best core material might be for a particular application
depends heavily on the operating frequency.

For the original poster, you might want to look into powdered iron
toroids, assuming your frequency is not too high.

I like the tantalums that come in the metal cylindrical cases with the
glass seals. I've never seen a bad one. Look for them at swap meets
and use them instead of small alum electrolytics as a higher
reliabilty replacement.

I've not had a lot of experience with the teardrop tantalums, but I
have seen a few bad ones.

While you will see aluminum electrolytics in all stages of ageing from
perfectly good to dead short or open, my impression of the teardrop
tantalums is that they are either perfectly good or completely bad.
There doesn't seem to be any middle ground.

It would be nice to find a set of bath tub curves on each kink of old
tantalum. Maybe we'll get enough inof here to sort the good from the bad.
I don't even have a cluse as to how many mfgs there were and how many time
they improved their designs as they experienced failures. Iguess what we
need to know is which one fail themost.

It is FT82-75 and the resistance is only 5 KOhm, so the mix is accurate.

I will have to make use of them in wideband tranmission transformers.
Can you folks suggest a frequency range?

I can get ferrite #61 or #63, but iron core only comes in mix #2 or #6
locally.

Thanks for all the help!

Mix #2 should be OK for your crystal set.

With a transmission line transformer you should be able to go up to 100
MHz or more, the core is only important at the lower part of the
frequency range.

I like to try the quasi sync circuit with a limiter and product detector on
AM band. Will this work with a TRF receiver?
This probably won't work with weak signals but has anyone tried this?

I'm also looking into a SDR. Basically the computer and soundcard can do
the sync using DSP.
This work be interesting for a HAM or SW receiver.

Pete

Go to the makers catalog (available as a big PDF) at:
http://www.fair-rite.com/fr_catalog-14thed_rev3.pdf
and read about the various types (starting with the parametric
comparison on page 4, including the frequency recommendations under
the low flux density row). Type 43 is normally used in RFI absorbing
devices but has pretty good properties for indictors for low flux
applications up to 10 MHz. Type 60 is recommended for up to 100 MHz,
and type 63 isn't a Fair-Rite type listed in this catalog. In the
same table type 75 is limited to .75 MHz for low flux applications.
Based on this table, alone, I would probably try the type 43.

Here's what seems like a hi-Q a crystal set using toroids:
http://www.crystalradio.net/contest/paul.html

It uses "two toroid cores, Palomar Engineering T-130, broadcast band frequency material". Unfortunately it doesn't say the kind of core, but from the number of turns and the capacitance I figured that it must be type 26 (yellow/white). I think this is a rather uncommon kind of material, it has one of the highest mu's, 75, compared to mu=10 for type 2 and mu=8 for type 6. Anybody with experience with this kind of material?

Vector used to have the T30 and T32 series of terminals that were
spring loaded, but they weren't on their web site when I checked today.
Maybe one of their competitors like Keystone or OK Tool. Or perhaps
some East Asian company. What do to they sell for prototyping stuff
in Hong Kong?

>Thanks for all the help!

Digging out an old Amidon spec. sheet, they used #61 and #33 for their ferrite (antenna) rods. Type #61 for medium wave and up to 10 MHz, and type #33 for VLF.

The real question is "Are you using it in a tuned circuit?", where you want the coil loss to be negligable. If you're making an antenna coil that's tuned with a capacitor for AM broadcast (.54-1.7 MHz), use the type 61.

For wideband transformers, where frequencies are higher than tuned circuit use, Amidon specs type 61 as good for 10-200 MHz, and type 63 as good for 25-200 Mhz. For HF use #43, #77, #72, or #F.

I recall seeing them some years ago, used for breadboarding and
experimentation. Try the usual suspects like Newark.

I would expect them to be problematic at higher frequencies.

It was an article in Wireless World describing AM receiver with
MC1330P8 - suppose it was sort of TRF, but I never had any success
with it, while MC1351P worked far better

So all I need is a limiter and a double balanced mixer.
Well I do have a SA602. How does one make the limiter from discrete transistors?

I wish to avoid very old/obsolete ICs.

Pete

An obvious point about using it as a TRF is how much selectivity will
you be putting at the front end?

Any time you are using a mixer to convert down to audio (as with SSB
or synchronous detection of some kind for AM), you can get selectivity
at audio, since it's a frequency translation.

But, if you've just got a limiter open to the world, at the very least
it's going to limit on the strongest local signal. If you don't have
enough front end selectivity, I would think you would get relatively
little tuning ability. The strongest signal will "capture" the limiter,
and that will be the "carrier" that beats against the incoming signal
in the mixer.

When people made synchronous receivers out of the old Signetics analog
PLL ICs, at least the PLL had a lock range that provided "selectivity".
so they could run with little or no front end selectivity. Except for
mixer overload, what you got out of the mixer was limited by the audio
circuitry and your hearing, since only one frequency (plus the image)
could convert down to say 0 to 3KHz from the oscilaltor frequency. The same
applies to direct conversion CW/SSB receivers.

A quasi-synchronous receiver will work the same way, in that the output
of the mixer will be within the audio range from the "carrier" out of
the limiter. But if you have no selectivity on the input to the mixer,
enough to separate out signals, then the strongest signal into the
limiter will prevail.

Much of what I've seen about "quasi-synchronous" detectors have placed
them in the IF of a superheterodyne receiver, where the IF bandwidth
ensures that it only reacts to the wanted signal. The only TRF that
I can think of seeing was in an old Technical Topics book from the RSGB,
where there was an MC1330 (which is a quasi-synchronous detector, for
TV use, though I believe the datasheet simply calls it synchronous)
as the detector, but there was an stage of amplification (I think
an MC1350P) ahead of it, with a couple of stages of tuned circuits.
With a quasi, you do indeed need some TRF before the detector.

If you English only types absolutely have to know what a message in another language is saying -- use a language translator like this one at URL: http://babelfish.altavista.com/translate.dyn

Not perfect but gives the essence of it all.

If you post in other than English -- the above URL will translate to English for you if you wish to reach a wider audience.

But perhaps the post below in French was intended for French readers only (:-)

Hi Henry,

I like what you write about test equipment. I have a nice collection of HP stuff of my own. Maybe even more than 40 items. I like HP because it was well known at my university at that time (the 70ties). Also it is well documented and it can be repaired at times. There are many other good brands available but I prefer HP. On the other hand: a lot of HP equipment needs repair at present. And indeed: the power supply is the culprit in many cases. Either tubes or caps. About tantalum: not much specific experience available over here, but I seem to like the axial metal ones with glass sealed terminations. So keep up the good work!
Btw: is there a site or community to exchange experience on how to repair HP equipment and how to obtain spare parts?
regards,
Harke PA0HRK

I have a book around here, somewhere, by Mark Twain entitled "The Jumping Frog, in English, then in French, then clawed back into civilized language once more by patient unremunerated toil." In this book, Mr. Twain writes about an article in a French periodical concerning Mr. Twain's Jumping Frog story. "This gentleman's article is an able one," Mark wrote, "(as articles go, in the French, where they always tangle up everything to that degree that when you start into a sentence you never know whether you are going to come out alive or not)."
I'm not an English only chauvinist. Whenever I come across a posting in French
I politely say "gesundheit" and go on to the next post. After all, there's no honor in
making fun of a man with a cold.

Hi,

I'm going fast and furious into building things, which is the reason I am posting
so much. Latest project is a variable power supply.

Situation: Radio Shack wall transformer with 11 VDC unregulated output is going into an LM371. I want to shunt with a pair of 5.1 V , 1A Zeners in series
so that my adjustable output voltage is repeatable. Presently my Zener series resistor is 180 ohms.

Problem.. I'm frying my zeners!!

What should I be doing differently?

Thanks in advance,

The Eternal Squire

=======================
Would you please indicate where the 2 Zener diodes (in series) are located
in the circuit .
Before or after the LM317
If before the LM317 why ? The LM317 provides excellent regulation even with
fluctuating 'upstream' voltage.
What is the LM317's adjustable output voltage range. And which max current
are you drawing ?

Are you sure the zeners are 5.1 V,1 Ampere and not 1 Watt. If the latter is
the case the permissible current must not exceed 200 mA. .

For getting best reliability ,I would suggest you load LM317 with a current
less than 0.4 Ampere .
If more current is required use a 'wrap around ' PNP power transistor.
This is described and shown on page 1.15 of the book : Experimental Methods
in RF Design ,by W7ZOI,KK7B and W&PUA .

Hi guys,

I've just been doing some calculations out of sheer curiosity. It
turns out that to make a tank circuit for 450Mhz (which isn't *that*
high a frequency by today's standards) would take 5pF || 25nF. These
are both *very* low values. 5pF is getting perilously close to being
seriously affected by circuit board stray capacitance and 25nF isn't
much better; little more than a couple of turns of wire, I guess.
What does one do in such circumstances? Should one be thinking in
terms of etching these values out of the PCB by the time one gets of
to these frequencies, or is it still acceptable to make them up out of
discrete components?

p

Don't you mean 5 pF || 25 nH? You could probably use a single turn or a
hairpin (1/2 turn) inductor and capacitor. It's quite workable at 450 MHz.

You can buy surface-mount caps below 1 pF and inductors below 1 nH, so
a discrete LC is perfectly feasible at 450 MHz. Even with a couple of
pF of circuit stuff - say, the gate of a gaasfet or an IC - you should
still be able to make a resonator or a filter up there. A small
trimmer cap or varicap would help nail the resonant frequency.

PCB capacitance for 0805 or 0603-size parts is pretty small, and you
can keep connection inductance in the 1-2 nH range.

Helical resonators are nice, too, as are coaxial ceramic resonators.
450 MHz is sort of in the transition region between discrete and
distributed resonator domains.

You need to first know the maximum and minimum current that your circuit will draw, then you can design the zener part. While this is over simplified, it should give you a start in the right direction:

The zener is sort of a current buffer in that it will absorb the current NOT taken by the load when the load is drawing its minimum current. Start thinking like this:

When the ckt being regulated is drawing maximum current, the series resistor in the zener leg is sized to provide a low zener current. When the ckt is drawing minimum current, all that extra current (the difference between the maximum and minimum current) goes through the zener. If it is too much you either need to get a higher dissipation zener, go to an amplified zener or some other regulator type.

Paul,
Once you get to these frequencies, it's often better and easier to use transmission lines (microstrip) rather than lumped LC components.

What is the application?

Hi Paul,

I'm currently experimenting with VCO circuits (had an earlier thread about varactors). My current prototype uses a MPF5179, a pair of BB909 tuning diodes and a home made inductor. The inductor is about 4 turns on 0.25" centre (air cored), spread out to about 0.4" in length, giving about 150nH. This circuit operates to 350MHz and (if the tuning diode info is OK) indicates strays of less than 1pF. This is built "dead bug" style, and is really my first attempt at anything of this sort of high frequency.

I'm sure with a little care 450MHz is quite achievable.

James.

I haven't actually built anything out of it, but the ARRL UHF experamenter's manual seems to be well written. Get a copy if you're serious.

In general you get to a frequency/power level where you need to toss the notion of using discrete componants and start using distributed (i.e. some variation of a transmission line) instead. This happens sooner at higher power levels (1500W amplifiers start showing plate lines at 2 meters).

One of these days I _am_ going to build some VHF circuits -- really!

I think that US "800" numbers don't always work from outside the US;
I just called them and got their local number:

513-868-6399.

It's gonna cost you, though. *sigh*

Hi

A question.

Would the in-circuit losses for RF equipment operating around 1 - 3 GHz be greater if built on 1.6mm or on 0.8mm FR4 laminate?

In particular, on which laminate thickness would a VCO in this range be easier to get running?

Any explanation for the answers would be helpful.

Thanks

MikeN

Hi,

Try a hairpin loop.

Transmission lines are still quite large at 450MHz and one less than a quarter-wave will have the inductive reactance necessary to resonate with your 5pF. The beauty of them is that you can tap up and down the line quite easily and variable coupling is a doddle.

Should they work out to be somewhat on the long side for the board, double them over. Some old ECM transmitters I came across had what looked like a conventional centre-tapped tank but which were really rolled up lines.

Cheers - Joe

Yes, but as you've deduced, the problem is keeping the clocks synchronize.

On the other hand, there's no reason you can't have one unit send out a pulse and begin timing. The second unit receives it, immediate sends a 'reply' pulse, and you stop your clock when the first unit receives that. Now the accuracy is determined by the accuracy of just one clock, the amount of uncertainty in the 'turnaround' time of the second unit... and the variation in the speed of light as a function of athmospheric conditions. (The last one being more of a concern if you're trying to listen to satellites -- GPS receivers run into this problem.)

You can also use multiple transmitters with high-quality clocks and one receiver -- this is what GPS goes. The transmitters send out a message saying, 'I sent this at exactly this time... really I did!' You record on your local clock when you receive those messages and hence can perform triangulation to determine your position. Better yet, if you have yet another transmitter, you can solve for your position as well as the _relative error in your timebase_ and thereby synchronize one (or more) receivers to the high-quality clock in the transmitter. In GPS receivers, this additional satellite is what gets you a 2D fix vs. a 3D fix.

> signal strength perhaps?
> literally I am talking about a transmitter within a cuboid shaped
> enclosure around 10m maximum and being able to pinpoint that transmitter
> within that enclosure accurately, to around 1cm, perhaps 2cm.

Ah, OK, if it's enclosed field strength would be a reasonably reliable indicator. There was an article in Circuit Cellar Ink just a year or so back where a guy did this (and cited references -- the idea has been around for awhile), but it's sort of the oppposite of what you suggest: You stick large (transmitting) coils at the edges of your box and then detect the signal strength on a small receiver. 1cm in 10m is 1 part in 1000, which I would gander is right about in the middle of 'trivial' and 'pushing impossible.'

There are also '3D' computer mice (mouses?) out there that use a couple of ultrasonic receivers on the 'mouse pad' and perform triangulation after listening for the mouse's transmission. Same idea as with RF, but easier because sound waves are so much slower than electromagnetic waves -- times are measured in microseconds or milliseconds rather than picosecond and nanoseconds!

---Joel Kolstad

That's basically how GPS works, except that you need more than one transmitter, or veddy expensive clocks in the receiver. Basically with GPS you receive accurate time signals from four satallites. Since your receiver doesn't know the time or it's position you have four equations (from four satellites) in four unknowns and voila! you have an answer. You can do differential GPS down to millimeter accuracy if you sense the phase of the carrier.

Loran uses the same basic concepts (synchronized transmitters, speed of light, yadda yadda), but it asks you to sense the phase difference between a master and a slave TX, and it isn't nearly so accurate.

I looked on the www.fluke.com web site and it says the Fluke 27 has a
limited lifetime warranty. http://www.fluke.com/service/warranty.asp
Might do well to drop them an email with your meters serial number
and description of the problem. I had a Fluke 75 from my job repaired
over a year ago and it was still under warranty. The job owned it for
over 3 years before I got there.

Are you sure the zeners are in the correct polarity ? Also I have not
looked at the way zeners are speced lately but aren't they specified as
Watts instead of Amps ?

671. distance of radio transmitter from receiver

Hi guys,

ok, I've got an idea but it's based on determining the distance of a transmitter from a receiver, I originally thought about a synchronised clock in both units, the transmitter sends the time it has out, by the time the receiver unit gets this time a period has passed (probably a few millionth's of a second) and a diff time is detemined, combined with the speed those waves travel, will reveal the distance.

however, physics decided this idea wouldnt work, since all electromagnetic radiation travels at the speed of light, apparently, DAMN, back to the drawing board.

I'm here to see if anyone has any way they can determine the distance from transmitter to receiver, this isnt a great distance either and it needs to be fairly, accurate, if it's not possible, it's not possible, I just wanted to ask people far cleverer than i.

signal strength perhaps?

literally I am talking about a transmitter within a cuboid shaped enclosure around 10m maximum and being able to pinpoint that transmitter within that enclosure accurately, to around 1cm, perhaps 2cm.

like I said, if it's not possible, well then hey, thanks anyway, but perhaps it is and therefore perhaps my idea will still be workable.

thanks guys! I'll be waiting for your answers or solutions

672. Re: FR4 Laminate RF losses

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-27 04:25:37 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <101bq2468ruqh24@corp.supernews.com>
Source record: 29259

Loss will be greater on the thicker board, because a greater fraction of the fields surrounding traces and components will be in the board material as opposed to being in the air. Having less field in the board material will also make your circuit less sensitive to the temperature and humidity dependency of the board material. The actual amount of loss or temperature/humidity sensitivity depends on a whole host of factors, so it's hard to say how much difference it'll really make in practice.

This is correct as far as dielectric loss is concerned, but copper resistive
loss decreases as the board gets thicker. Which one will dominate depends
on frequency and characteristic impedance. At low frequencies, dielectric
loss will probably dominate. At high enough frequencies,
copper loss will dominate. For low enough impedance traces, the
field will be mostly in the air for either board thickness. Complex
problem to analyze.

But, it makes sense that some businesses in the US would want
Canadians to have access to a US 1-800 number.

On the other hand, this is not automatic. Plenty of times I've
heard a 1-800 number mentioned on the radio, and then the host
says "wait, that's not useable from Canada".

Some 800 numbers only work within the state where the number is
located.

This is a typical application of an acoustic positioning system. With a speed of sound of about 340 m/s, this is feasible. I have made such a system with acoustic tags on 40 kHz using 8 receiver nodes in the room. That's more than required, but it gives enough redundancy to be robust against shadowing as things move around in the room. Accuracy is in the 1-2 cm range.

Since the measurement should be done in a confined space, why not
switch the roles and use one transmitter on the moving object and four
receivers on known fixed locations around the perimeter of that space?

With the receivers connected by cables receiving a common clock
signal, the accuracy of the clock is not important, contrary to the
situation in GPS, in which the four satellites must have atomic clocks
to have a common time base.

>Loran uses the same basic concepts (synchronized transmitters, speed of
>light, yadda yadda), but it asks you to sense the phase difference between a
>master and a slave TX, and it isn't nearly so accurate.

Space probe ranging is done by sending a high data rate pseudo noise
sequence from earth to the probe, in which a simple frequency
translation is done with a high accuracy local oscillator to a
different frequency and sent back to earth. From this, the total
earth-probe-earth phase difference of the PRN sequence (and possibly
also the total RF phase difference) can be determined and hence also
the distance.

However, in this case the accuracy requirement was 1 cm, so I guess
that at least 10 GHz (3 cm) radiation should be used.

Two 5.1V zeners in series, fed through 180R from 11V DC, can only be dissipating about 20 milliwatts each. In that circuit, they *cannot* fry.

Conclusion: something in the way you described the circuit *must* be incorrect. Once you've realised that, the problem shouldn't be hard to find.

Yes, all of the above... and 0.8mm ("1/32in") FR4 also has many
practical advantages for home constructors.

One is that unlike the regular 1.6mm board, you can cut 0.8mm FR4 easily
with hand shears - or even strong scissors - without significantly
damaging either the board, the shears or yourself.

The thinner material is not as resistant to flexing as 1.6mm - it's
about as flexible as a credit card - but that's still strong enough for
most purposes. If it's an RF circuit, and you're going to add shielding
walls of hobby brass strip all around the outside, the resulting
assembly will be very rigid.

50-ohm microstrip on 0.8mm FR4 is about half its normal width on 1.6mm,
which makes it a much better match (in all senses) to the width of the
SMD components hanging off the ends. It's still wide enough to make the
impedance reasonably insensitive to HB fabrication tolerances.

Since 0.8mm FR4 is the basic material of multi-layer boards, increasing
numbers of PCB materials suppliers and board makers can now offer 0.8mm.

In the UK, Mega Electronics supply both SS and DS photo-resist-coated
0.8mm FR4 (and also many other specialist PCB-making materials):

What's the mechanism for the copper loss decreasing as the board gets thicker? Of course, if you assume that the traces consist only of microstrip or stripline transmission lines with some fixed impedance, then the line width will be greater on the thicker material, resulting in lower loss. Is that the rationale, or is there some other phenomenon at work?

The 8xx number is a toll free number -- the terminating location pays for the call. When the number is originally provisioned by the telco that is providing the service, the client can specify locations that they are willing to pay from. Typical combinations are instate only, USA only USA/Canada/Mexico/Carribean. R&L is probably rejecting any inbound calls originating ovewrseas.

You don't necessesarily need to have a carrier wavelength smaller than the distance you want to measure, as long as you can accurately measure phase. Assuming that you could measure phase to 10 degrees, for instance, a 1cm accuracy would only require 900MHz (33cm).

Surveyor-quality differential GPS uses the 2.4GHz GPS carrier and measures the differences in the carrier phase (not the phase of the pseudo-random sequence) to get sub-cm accuracies.

A possible solution is (if those are still made), the "springs" used in cable harness wiring boards. Those are conventional springs with wide spacing, the ends slammed into nail-like points. When literally hammered into a wooden board, the springs still allow some flexure enough to hold an insulated wire in place.

Not a good solution since the turns on the spring are wide and I've never seen the spring surface plated with anything resisting corrosion. Those are (or were) quite cheap but available only from a few vendors. [I was in R&D, not in production...]

The push-into-place, hold-wire-ends-by-friction prototype bread-boards seem to be quite popular with hobbyists. Most of those I've seen are made offshore. Those are easier to use, hold as tightly as cable harness springs and have their own "backing board."

Yep! acoustic is one. another is infrared

Over this short distance RF travel time is in the 30 nano second range.
This requires some pretty good timing measurements. Sound, on the other
hand, has a speed of around 30 mili seconds for 10M (30 ft).

Something I wanted to do for a long time is a model rocket altitude system.
Rocket has a one transistor 10M Rx (have the circuit around here from some
1960's Pop Electronics for a 1 tranny FM broadcast Rx) and a one or two
transistor 2M Tx (FM) -- rocket antenna easier.. Ground station on 10M
(lots of power available for the wooden rocket Rx) transmits a TONE (not a
pulse). Rocket transponds (retransmits it on 2M). Measure the zero
crossing time delay and subtract the overhead time. With proper (and
simple) digital design, you can have a digital readout in feet, inches,
whatever. With a tone, common ham radios are just fine.
With audio, pulses are easy except how do you keep the target from hearing
it's own echo and "oscillating by itself...?

or use subcarriers - this is a little harder. Transmit an FM modulated tone
(carrier, say 10KHz, tone 1KHz) and transponding it back on another
carrier, say 15 KHz.

Who was it that used to sell the sonar modules from the cameras for
experimentation

acoustic

my problem with this is that radio waves are electromagnetic radiation
which travels at the speed of light, therefore can travel 1 meter in 3.3
nanoseconds, if my range is around 10 meters (I was a bit conservative
before, lets say 30meter width/depth and 10 meters high, that'd be big
enough I think for any situation I'd use this system within.

Is there a clock out there that can measure accuracy on this scale, it
seems impossible. That's of course, if radio waves travel through our
atmosphere at almost the speed of light, I'm going to look now as to how
fast they travel through our atmosphere.

> receivers to the high-quality clock in the transmitter. In GPS receivers,

> this additional satellite is what gets you a 2D fix vs. a 3D fix.

well if you have one transmitter attached to say the top of your head,
you'd need multiple receivers to be able to triangulate that
transmitters position wouldnt you, you'd record the time it was sent and
diff it against the time you have in your local clock, that difference
would give you a rough distance to the transmitter, from each receiver
you'd have a distance/transmitter value, which would denote the RADIUS
of a circle from which the transmitter could be, of course, the location
of the transmitter is where all three circles overlap. More receiver
units could be used to increase the accuracy of those measurements.

the problem again is clock sync. I did originally think that you could
have one master receiver unit, whose clock all others are determined by,
this clock could send out it's time with a "reset" code that all the
other clocks would reset their time to, this would happen fairly
accurately would it? I think it would. Then you're clocks are fairly
sync'd. You'd probably not want to run them for long without resync'ing
again though

"Losses" due to substrate material don't begin showing up until
one gets into S Band (above 2 GHz or so). All of that microwave
stuff is rather old hat to the short wavelength folks, in texts for
over 3 decades...but expensive to collect due to textbook costs.
:-)

I've "designed" directional couplers, hybrids, Wilkinson dividers,
etc., (at 1 GHz) by simply copying textbook instructions while at
Teledyne Electronics, a place where lots of folks were busy with
distributed constant structures on stripline. The watchword ought
to be Dimensional Stability rather than "losses." In that case,
Duroid (Teflon-fiberglass) is a better substrate. That isn't needed
at 400 MHz and below since the "losses" in any circuit down
there are in the components, not the substrate.

The sole exception to "losses" is the case of substrate problems
such as I encountered at Hughes Aircraft way back in 1957, new
to southern California aerospace. Hughes had subcontracted a lot
of terminal board assemblies for airborne radar and was suddenly
encountering way-too-low insulation resistance in some assemblies.
At the time that was important to the relatively high impedances of
vacuum tube circuits. After organizing the lower classes in several
shifts and tying up every MegOhmMeter in the corporation, a crash
round-the-clock testing discovered a single fabricator being the

culprit. Said fabricator also made rubber products and some of the
(carbon?) dust in the fabricator's air system was drifting through
their plant and settling on the substrate press where they finished
raw "circuit board" material. Fine for overtime (one of the last
places where I got any overtime in the career) but a pain in the
posterior and most boring and dull to do. Problem solved and
the radar sets got finished. [weird old anecdote]

>One is that unlike the regular 1.6mm board, you can cut 0.8mm FR4 easily

>assembly will be very rigid.

Whether shielding or not, a simple strip of copperclad soldered in
perpendicular to the circuit board adds enormous stiffness and
dimensional stability.

I just uncovered the motherboard-backplane to a Midwest Scientific
6800 microprocessor kit in a workshop storage box. It used strips
of copperclad soldered to the backplane +5 VDC and ground traces
(roughly 0.37" wide). It had been in the box better than 20 years and
at a diagonal, other parts putting weight on it as if to bend or bow it.
Sighting down the surface, it was still as flat as it was when I put it
together two decades earlier!

>50-ohm microstrip on 0.8mm FR4 is about half its normal width on 1.6mm,

>
>In the UK, Mega Electronics supply both SS and DS photo-resist-coated
>0.8mm FR4 (and also many other specialist PCB-making materials):
>http://www.megauk.com

One of my personal gripes is the cost of basic copperclad at dealers.
In bulk quantities the material is quite cheap in anyone's monetary
units, yet the dealers mark the prices up well above bulk cost. The
excuse is "cutting to manageable shipping size" and other mythology
to disguise getting as much for it as they can. :-)

I've found that true in the USA, especially around southern California,
once one of the aerospace centers and a big user of copperclad.
The few Canadian dealers doing mailorder have better prices for
copperclad than in the USA. I've gotten "surplus" copperclad (when

spotted with the bargain-hunter's eye) in sheets at less than a tenth of the price of cut copperclad from dealers. A small fee paid to a sheet metal fabricator and they will use a shear to cut such down to manageable size. Overall copperclad cost that way is still less than a tenth of dealers' cut copperclad prices.

The four-sided box type of circuit board shielding will do wonders for physical stability once soldered in place, even with the thin 0.032" thick single-sided copperclad.

in the early 80s I built some narrow band VCO employing a 450MHz Toko
helical resonator bandpass filter.
The trick was to get the phase including amplifier and a varicap phase
shifter to zero.
I recall a -125db /rootHZ at 10kHz with a bfr bipolar.
Never got anything better though was narrow band.

Here's one for you microwave guys...

I'm looking for any kind of info, specs, etc,
for a Varian model 212MS microwave YIG filter.
The data plate on the unit says it covers the
freq range of 1.8 to 12.4 GHz. It has Type N
connectors for input and output, and solder
pins for the DC control voltage. It came from
an old piece of HP test equipment. Anyone
have information on this filter? I was unable
to find anything on the internet using Google.

700. 2m Amplifier Designs

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-28 00:25:15 UTC
From: Jason Dugas <kb5urq@hotmail.com>
Message-ID: <101e0dhcjasuncf@corp.supernews.com>
Source record: 29287

I was looking through my old 1994 ARRL Handbook at the 2m amplifier designs. I thought the few they had there were interesting so I decided to look in the only other handbook I had (2000). I was stunned to see that there were NO VHF amplifier designs included. Even funnier, was the absence of the amplifier topic altogether in the VHF/UHF handbook-- no designs there either. where are they all hiding?!?!

If anyone has some good designs on the net, please point me to them!
Thanks,

Jason

Don't mean to beat a dead topic to a second death, but in case you wanted to know NASA uses tantalums extensively as replacements for electrolytics on-orbit (on station & shuttle). I don't can't recite the reasoning verbatim, but it is an M&P (materials and processes) issue, having to do with operating at low pressures and also the dangers of electrolytics entering various failure modes due to overheating in space (no bouyancy-driven convection). Tantalums tend not to fail catastrophically (pop or explode) when thermally stressed.

704. Need help decoding rtty signal

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-28 01:21:05 UTC
From: hexter@blazenet.net
Message-ID: <101e3k1rab1tlf2@corp.supernews.com>
Source record: 29291

There are four very strong signals here on the east coast of U.S.A., I here them best after dusk.

3.084mhz 3.102mhz 3.126mhz and 3.132mhz

Here is what I know,

1000hz center frequency
850hz shift
75baud / 13.3ms so it would appear

The signal stops erratically on both space and mark tones. Also, at times the baud rate seems like it becomes very fast, perhaps double.

I hear this same exact 'signature' signal in many places, on many bands, and can't seem to decode it with normal 5 level baudot programs. However, the signal doesn't seem to be ascii either.

Anyone want to give a listen, and tell me what I need. Are they encrypted, or do I just need a different rtty-to-text convertor?

(Jason replied to me via email):

Hmm, guess they must have skipped a year on the topic...
Does the 1.5kW linear require an external high voltage power supply? the
300W unit in 1994's handbook requires fabrication of both the amplifier &
the power supply..

Jason
KB5URQ

It requires one, either internal or external. If you can put the RF deck
together then you should be happy putting together the HV supply (may want
to buy a crane for the transformer, though).

Don't know anything about this particular unit,
but the frequency should be linear with input current.
Measure the frequency at two currents and you should
have what you need. For reference a 2-6 gig yig
oscillator (at least mine) is 20MHz./mA.

It was Polaroid.

You can get sonar measuring devices at home handyman stores for a few bucks. They might be useful with a little hacking.

Can anyone tell me how detailed the schematic diagram in the manual is? I can't afford to buy the loop, but am pretty good a cobbling and crafting and coming up with something that works. Is there a kind soul out there who is willing to scan and email a copy of the manual? Perhaps I could build a workable clone from the circuit details in the manual. I'm also looking for closeup pictures of details of the loop and circuitry - anything that would help in producing a viable clone (they don't make 'em anymore).

Communications Concepts is a company that supplies parts and whole kits for making a number of solid-state RF AMPLIFIERS, principally made according to Motorola application notes done mostly by Helge Granberg. C-C has some of those app notes available for download although the quality wasn't good when I checked them out about 3 years ago. I've heard good words about C-C but never ordered anything from them myself.

Some of the old Motorola app notes still exist in downloadable form from the archives of the Motorola website...or at least existed at one time. Some of the old Motorola RF amplifier transistors are now made by ON Semiconductor but the original Motorola solid-state organizations did a rather monstrous downsizing of production to more in-demand and profitable semiconductors.

For some background on an established system, research aviation
navigational aids DME (Distance Measuring Equipment, civilian use)
and TACAN (TACtical Area Navigation, military use) for an aircraft
to get their slant range to a ground station.

DME, compatible with TACAN for range, has an aircraft interrogator-
receiver that sends a pulse pair at low L Band. A ground station

within range will receive that pair, wait 50 microseconds, then respond with another pulse pair. The aircraft determines range from the round-trip to get a response minus the fixed 50 uSec delay using the common radar round-trip time (which is approximately 500 uSec per mile for coarse estimation).

The reason for the pulse pairs is to avoid false responses and returns from noise spikes or stray single pulses or whatever. That is easy to implement by a delay line and the equivalent of an AND gate action. Single pulses won't get passed but a pair with the right spacing will.

To further cut down on false replies in a crowded airspace, the aircraft interrogator repetition rate is "dithered" slightly. Since the aircraft uses that interrogation as the start of its timing to a return, the dithered rep rate doesn't matter to it...but to the rest of the air-space, those interrogations and replies seem like so much noise from others ("fruit" in the civil avionics jargon).

TACAN has been in the U.S. military since the early 1950s (a USN development) and DME came shortly thereafter. Used daily by aircraft on civil airways. Accuracy depends on the calibration of the aircraft interrogator-receiver. Old ground stations used a supersonic delay line filled with mercury to achieve the fixed 50 uSec delay of replies to an interrogation from aircraft. Maximum duty cycle is rather higher than radar for ground stations but not a real problem. That fixed delay includes the turn-around time of receiving a pulse pair, determining that it is a pair, etc. A fixed delay allows checking out the system prior to takeoff, using a local VORTAC station at close range.

==========

Trying to use one-way signal strength for range isn't going to be good. If within 5 to 10 wavelengths for the path, the path is fraught with all kinds of variations just as a parasitic antenna works with field phasing. Unlike parasitic antennas, the path would not be straight line (such as a Yagi-Uda).

Beyond the "near field" effects, one would get Multipath reflections, some of which would be in-phase, some out-phase, all resulting in many decibels of strength variation at short relative positions.

Signal strength as a coarse distance indication is only good at very long ranges relative to wavelength. Even then it is uncertain. It's very difficult to get a true isotropic source with a spherical radiation pattern in a practical antenna, any RF wavelength.

Round-trip time is the only practical way to achieve ranging whether by RF or by acoustic means.

New location systems based on WLAN (2.4 GHz) use field strength combined with what seems to be some sort of adaptive algorithm that learns the field strength vs environment through repeated tests. See www.ekahau.com and www.radionor.com. These companies promise location for 'free', as they can locate laptops by using the existing hardware infrastructure of the wireless network. This is a very hot topic these days, and large business opportunities are expected.

But accuracies are in the 1 m range, to get to 1 cm accuracy there does not seem to be any alternative to ultrasound systems, see demo on www.sonitor.com.

We did a unit at my last job called 'velocity of light'.

It was pretty simple and you cud accurately measure distance down to 1cm.

Infrared led emitter switched at 50MHz, focused using a lens to a 2 inch beam, reflected back by a mirror to an infrared detector (5 inches away from the emitter).

The tx 50MHz was generated using a 50MHz xtal which drove the tx led.

Their was a 50.025MHz second xtal osc which was used to mix down both the tx signal and the rx signal to 25KHz IF (we now have 2 25KHz waveforms), these two 25KHz carriers were then phase compared - so easy to see the smallest of movements in the mirror on a basic scope.

So all the hard work is done at 25KHz (phase measuring) - one of todays little mcpu's will do this easily (ATmega16 for example).

You could just as easily use laser or maybe rf in place of the IR led's, though directing RF at such low freq's would be somewhat difficult.

Obviously at 50MHz, the phase difference would cycle every 6 meters (total reflected path), but if your a bit cleverer (though not hard to do) you could get the freq to sweep from a low freq (say 5MHz) upto wot ever you like - using a pair of single xtal referenced PLL's to generate the two oscillator freq's (whilst maintaining the 25KHz difference) and then calculate an exact distance in the cpu.

This method is simple and relatively cheap to judge distances very accurately with no need for very short pulses (high bandwidths) and very fast logic.

Clive

Forgot to say.

A 90deg phase change in the reflected beam (at 50MHz) also results in a 90deg phase change in the rx'ed 25KHz IF) - this is why no fast logic is required.

721. Time to update some datasheets

Source record: 29109

If you keep the impedance constant, the loss goes down
for the simple reason you state that the width increases.
If you keep the width the same, the loss also goes down
because the characteristic impedance is higher. This is
because the copper resistance, relative the the characteristic
impedance, is lower. This is analogous to open wire line.
Suppose you make two OWL's with #14 wire. Suppose
one line has 1/2 inch spacing and the other has 1 inch
spacing. The 1 inch line will be lower loss owing to its
higher characterisitic impedance. OTOH, a #14 twisted
pair will be much higher loss due to its much lower impedance.

725. Parasitics in amplifier chain

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-28 21:03:14 UTC
From: kc0luy_usenet@comcast.net
Message-ID: <5bae94cc.0401281303.465db66b@posting.google.com>
Source record: 29112

Greetings All! I'm a long time lurker, but a first time poster.

I have been busy building a homebrew 20m SSB transceiver.

So far things are working fairly well, however, before I move on and Finish the final PA stage, I would like to solve a couple of mysteries with the driver stages leading up to the PA.

This is the project that I am copying: (Thanks to Ashar Farhan and to W8DIZ, for all of their help and patience with my questions!)

http://farhan.net.co.nr/xcvr1.html

I have made some component substitutions, added varactor tuning to the VFO, and I am using cascoded JFETs in the mixer instead of a single JFET.

My problem at the moment lies with the tx linear amp chain.

So far I have built up the tx chain to the point up to the final PA stage. I am using MRF517s instead of 2N3866s. I built the linear amp driver for this rig on a separate board not wired to the rest of the rig (so far). This consists of a chain of three nearly identical bipolar feedback amp stages. For my tests, I attached a 50 ohm load to the output of the third stage.

There are two strange things I have noticed about the transmit chain:

1) If the input to the first stage is shorted to ground through the coupling capacitor (grounding at RF, but not DC), then the amplifier will oscillate at about 45MHz. With a 50 ohm resistor grounding the input to the amp, it does *not* oscillate. (The amp has a strong peak in its gain around 45MHz, having twice the peak V as it does at 14MHz, could this peak be related to the parasitic resonance making it oscillate under the above conditions?) ((keep in mind that there are no tuned circuits (by design anyway!) in the amp and its not attached to any tuned outputs or filters yet.)) I've added 1K resistors across the bifilar transformers to kill parasitic oscillations, which they do an admirable job of with a normal impedance at the input. I've also used all monolithic ceramic capacitors for bypass, coupling, and emitter degeneration.

2) After I attached the amp chain to the rest of the rig and adjusted the mic level so that no clipping or over driving of the output was visible, I now have a residual carrier of about .5v peak when not speaking. The signal level at the input to the amp is too low to measure when not speaking. I substituted 1N5711s for the 1N4148 diodes in the

mixer, but I believe that is suppose to make it better because of the lower forward voltage drop and the faster speed of the 1N5711. The maximum output before clipping starts is 6V peak with 60mV peak input. Higher inputs drive it into distortion and clipping. Seems normal to me, but what do I know?

This amp is laid out very cleanly and constructed well. I have already eliminated parasitics from the amp when disconnected with no signal driving it.

With #1, I am concerned about the oscillation with the input shorted to ground because it seems related to the peak in the gain around the same frequency, even though I do not plan on operating it with its input shorted to ground, nor operating it anywhere near 45MHz.

Should I be concerned? If yes, some suggestions of things to try would be very welcome.

With #2, The residual carrier, I wish to eliminate or severely reduce it before I add the final PA section. I will appreciate any suggestions of things to try here too. BFO frequency adjustment? Bad mixer design? Bad mixer diodes?

I am not sure where to start looking for trouble on #2

All of your help and your suggestions will be most appreciated. I can supply photos of my layout and supply further details on where my implementation deviates from the original schematic of Farhan's rig, upon request.

Thanks in advance!

Hi, welcome! :-)

Something you can try:

1) place a ferrite bead on the base(s)

2) Toss a low value resistor (10 ohms or less) on the collector as close
as possible to the transistor.

Good luck!

#1:

Yes, the 45MHz peak with a 50 ohm source is almost certainly related to the 45MHz oscillation with the input grounded. You can try to fix it, or you can decide not to worry about it. Shunting the transformers will certainly kill the peak, but at the cost of some gain. If you're _really sure_ that you'll always present that amplifier with a 50 ohm impedance you're probably OK. If it was me I'd probably try hard to chase it down, but I'd go on the air even if I couldn't entirely fix it.

#2:

Where are you measuring things? Is this the input and output of the mixer, or somewhere else?

Did you adjust the carrier balance (that 100 ohm pot that the diodes connect to after T5)? It should be diddled until your carrier is at a minimum. I would be very tempted to put some resistance in to reference the audio to ground, but I'm not sure if it would improve anything.

You may also want to match the forward drop of the diodes, but with the carrier balance control such measures are probably superfluous.

Even what you have probably meets minimum standards (whatever they are), but you probably want to fix it before you fly.

729. Re: Need help decoding rtty signal

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-29 00:48:52 UTC
From: bg998@FreeNet.Carleton.CA
Message-ID: <bv9l9k$1k3$1@freenet9.carleton.ca>
Source record: 29116

You are right about the shift and keying speed (850 Hz at 75 baud). What appears to be a doubling of the keying speed is actually Mark-Space reversals, still sent at 75 baud.

The signal is not bulk encrypted but individual messages seem to be.

The reversals are sent before the beginning of a message and again after the end of it. I also observed periods of unmodulated carrier sent between periods of reversals, probably while the operator changed tapes or loaded another message into the computer or crypto device.

If I listened carefully, it seemed that the beginning of some messages contained a rhythmic pattern which lasted a few seconds. I looked for a frame pattern, out to 226.8 msec (the limit of my software) but found none, so this introductory pattern must be longer than that. Also I could find no frame pattern within the bits of a message (more evidence of encryption), out to 226 msec.

The freqs you mentioned aren't listed in my 2003 Klingenfuss list of utility stations, so I guess it is a relatively new station.

Have you checked the Worldwide Utility News (WUN) website?? (Sorry I don't have their URL.) Some of their monitors might be able to ID the station. (It's not in an exclusive Amateur band, so it's not a problem for me HI)

Tuned loop antennas for AM broadcast band are easy to build and work
well. Do a search for National Radio Club, a MW DXer association.
You can build a simple loop that works with your ferrite rod antenna
radio or spend more time on something with a FET preamp or mount it
outside with remote tuning.

I got good results with a 2 foot tuned loop with a shielded pickup
loop inside it. You should be able to find it on the NRC site.

Don't know about the Kiwa, but there are only so many variations on
the theme.

Two options:

Use a DDS chip like the AD9850 controlled by an MCU with a serial interface.

Use a PLL synthesiser controlled by an MCU with a serial interface.

Up for auction is a nice Zenith L515-W AM Tube Radio from the early 1950's, featuring a Telechron Clock with sleep control, and Bakelite case. It is in very good condition.

Ebay item number: 2221510600

Ted,
There are many manufacturers of compatible connectors and many different configurations. In general, they are referred to in the vernacular as .1" single-row headers, or .1" single row header sockets, or something similar. If you open a Digi-Key or Mouser catalog, you'll find many choices.

In order to recommend the right one for you , it's importamt to understand your application. Will the DDS board be PCB mounted or connected to a cable harness? If PCB mounted, do you want the DDS board to lay flat on the application PCB or at right angles to the board?

When you look at the catalogs you'll get a much better idea of the choices.

It sounds like there was one type that people were using, and it must have had something nasty in it. I firmly believe that a conductive spray paint could be made that is durable and environmentally safe, however.

Someone will come out with something to replace it, or already has so keep digging. Perhaps you should consider some clever kluge like contact cement and foil for your immediate needs?

It sounds like you just need to know for this one kit, but the designation "C0G" also indicates a zero temperature coefficient, it's just a different nomenclature than used with NP0.

For testing purposes, I have the DDS Daughtercard in a DIP socket that has wire-wrip legs. The socket fits snugly into the proto board and makes it easy to check out your newly built card.

I'd be mildly surprised if conductive paint has been banned, as IBM
uses _a_ _lot_ of it in their mainframes, to make the enclosures as
close to Faraday cages as they can get them consistent with having
holes cut in the sides and bottoms for cable access.

But if you mean "conductive paint in spray cans", that may be a
totally different thing. I'd call some paint manufacturers -- Krylon
and Rustoleum for starters. Probably they have "800" numbers that are
on the cans in the hardware stores, and "800" number information calls
generally are free.

YES! I recently purchased some of it to coat the inside of a plastic cased radio scanner to shield the inside chassis. Bought it from "Electronic City" located in Burbank Ca. Their telephone number is (818) 842-5275.
I'm not at home right now or I could get the can and give you the data from it. Hopefully the folks at Electronic City can help you on this...Eddie

The ARRL handbooks have these off and on -- no parameter computation, just things that work. The copy I have at my desk is 1976 (don't ask me why -- in 1976 they'd given up on tubes and were barely figuring out how to make decent solid-state circuits, but there you are). It has one for VHF/UHF, it's on page 636, and it's made mostly from copper pipe from a plumbing store.

The UHF experamenter's manual probably has something, too.

I'm not sure what's in current versions of the ARRL VHF/UHF manual,
but I know that older ones have articles on building SWR bridges. You
can just delete the detectors if you want to use them as directional
couplers. Also, you can download "RFSim99" for free, and you will
find in it a little design ap for directional couplers, in microstrip,
stripline, transformer-type, lumped and transmission line. The ap is
under "tools-->components-->coupler" in the pulldown menus. Note that
the microstrip and stripline assume the coupler is 1/4 wave long for
the given coupling--something the ap fails to point out.
Interestingly, 1/4 wave couplers (microstrip or stripline or the like)
give the same coupling at 3/4 wave...in other words, at the third
harmonic, which is useful for 146MHz and 440MHz. This is not true of
the lumped. The transformer style depends on the bandwidth of the
transformers.

Cheers,
Tom

I these kind of system it is the field strength that is the most important
not the distance. A radio system needs signal strength and that is the
primary reason to measure it. There is a desire to get distance from it,
but this is more of a dream rather tham reality. In cellular systems, it
can be used and give pretty goos location in SOME cases.

I say, for the described situation, RF is NOT the way due to the timing
requirements.

I think this will be easier than using RF. However, even though the IF is 25 kHz, you are still measuring small time differences. I just think this hardware will be easier than RF. Mostly because you can control where it goes better. This, of course, assumes you can do that in the target system The OP has to decide.

That being said.... oneof those 10 GHz door opener or motion detector units (does the GunnPlexer have a DC output from its detector?) would be another interesting method. You can easily see small motions in the reflected signal phase difference and this is at the 10GHz freq. so the resolution is high. You do need to insure that the desired reflection is the only one...similar to the LED type of system.

An aiming problem.

Forgot to say.

A 90deg phase change in the reflected beam (at 50MHz) also results in a
90deg
phase change in the rx'ed 25KHz IF) - this is why no fast logic is required.

You may need to look this up in the Klingenfuss Data handbook, many RTTY signals can be tuned in and received OK but are encrypted. There may be a copy of the latest edition in your library.

http://www.miller-stephenson.com/

Click on "Products", then on "Conductive Coating". Their MS-487N is a
nickel-based conductive paint, intended for RFI/EMI shielding.
Will attack acrylic, polycarbonate, polystyrene plastics. It's
available as a liquid but not as an aerosol. You might be able to use
it in a commercial airless paint sprayer.

Less formal solutions to the problem, which I have seen suggested but
have not actually tested myself, include:

- Carbon-based black spraypaint intended for high-temperature
applications such as woodstoves, stovepipes, etc.

- Zinc-based "cold galvanizing" spraypaint.

I have no idea what sort of attenuation you'd get from either of
these, or what sort of surface preparation, priming, or overcoating
might be required on various materials.

A person should always do a Google search before asking a question in a newsgroup. It's likely been discussed dozens of times before. This could make the question not needing to be asked in the first place - or, the asker could then ask with some background of knowledge.

You will very likely find more than you ever wanted to know about the subject by searching Google.

I'll add to that -- a lot of folks don't know that Google can search not
only the Web -- but Newsgroups and Images as well.
URL: Google http://www.google.com/
See search for -- web, -- groups, -- images, -- directory

A good example is oil for a Heath Cantenna (or equivalent)

This question appears every month or so.

But using google GROUPS -- type in Dummy Load Oil -- get hundreds of
useful (and so not useful) advice.

Want to see an ARC-5 Command set -- use images.

Great resource -- googles the mind
.

has anyone got the spec. on i think Philips made, pink top trimmers..they appear to be about 80pf, have a pink top.ptfe insulation.(i think).a black base.3 legs.the vanes being soldered to the centre pin..about the same physical size as blue spot;s but without thesquare frame...ie like the standard yellow 65pf trimmers...

looking for max voltage rating..
are they as good as philips blue spot???

cheers simon g0zen

All prices are in US Funds.

QTY. Part # Unit Price Description
---- --------- ---------- -----------
OPTO.

94 TIL311 $7.00 ea. The TI TIL-311 is a Hexadecimal Dot
Matrix Display with integral TTL driver
electronics to accept, store & display
4-bit binary data, Epoxy package
(Note: This part wholesales at about $16.50 each)

8 TIL311A $7.00 ea. The TI TIL-311A is a Hexadecimal Dot
Matrix Display with integral TTL driver
circuit to accept, store & display
4-bit binary data, Plastic package

11 DIS1417 $7.00 ea. The TI DIS-1417 is a Hexadecimal Dot
Matrix Display with integral TTL driver
circuit to accept, store & display
4-bit binary data, Epoxy package

For a copy of the TIL311 Datasheet see:
http://www-s.ti.com/sc/ds/til311.pdf and it is mirrored at
http://umwnt1.physics.lsa.umich.edu/mttc/images/til311.pdf

275 Green LED $0.10 ea. Rectangular 5mm x 2mm face/lens
$17.50 per bag of 250 ($0.07 each) and

8,250 Red LED $0.10 ea. T1 3/4, 5mm Diameter or 0.2" Diameter
Sharp P/N: GL5PR4 (5mA at 1.9V)
$17.50 per bag of 250 ($0.07 each) and
$100 per box of 2000 ($0.05 each)

106 MAN6440 $0.95 ea. Dual Digit, Green 7 Segment display,
0.56" tall character, Common Cathode
$15 per tube of 20 MAN- 6440 ($0.75 ea.)

85 FND6740 $0.95 ea. Dual Digit, Red 7 Segment display,
0.56" tall character, Common Cathode
$15 per tube of 20 FND-6740 ($0.75 ea.)

TTL CHIPS, DIP Package

525 7407N $0.18 ea. $4.00 per tube of 25 ($0.16 each)
Hex Non-Inverted Buffer with
Open-Collector outputs

605 74ALS20AN $0.19 ea. $4.00 per tube of 25 ($0.16 each)
Dual 4-Input Positive NAND Gates

240 74ALS27AN $0.19 ea. $4.00 per tube of 25 ($0.16 each)
Triple 3-Input Positive NOR Gates

1,325 74LS74AN $0.25 ea. $5.00 per tube of 25 ($0.20 each)
Dual D-Type Positive Edge-triggered
Flip-Flops with Preset and Clear.

100 74ALS74AN $0.25 ea. $5.00 per tube of 25 ($0.20 each)
Dual D-Type Positive Edge-triggered
Flip-Flops with Preset and Clear.

RESISTORS

55,000 100 Ohm, 5%, 1/4 Watt Carbon film resistor, $1 per 100,
$15 per box of 5000 or
$100 for 50,000 pieces.

3,400 220 Ohm, 5%, 1/4 Watt Carbon film resistor, $1 per 100,
$12 per box of 3400 or

3,400 680 Ohm, 5%, 1/4 Watt Carbon film resistor, $1 per 100,
$12 per box of 3400 or

A pack of 100 resistors is $4 inclusive shipping to anywhere
in the US and Canada

e-mail: jrparts@excite.com

Minimum purchase $4 including postage.

No shipping is included in the above prices. To quote a
total including shipping, I require your full ZIP code or
postal code in addition to a list of what you are interested
in. Please specify the country for international orders
outside of North America. The shipping you will be quoted
is the cost of the postage stamp (plus insurance if requested).

The only part that I will ship for a total of $4 (by regular
mail) to anywhere in the US and Canada is a pack of 100
resistors.

All components are new. All semi-conductors are stored in
anti-static tubes/bags or on anti-static foam if you purchase
less than a tube/bag.

Offers on the lot are welcome. Keep in mind that I am looking
for a price below wholesale, but more than the commercial buyers
of surplus electronic parts are offering.

Tnx Eddie for the tip. I called and ordered from your source.

To all the guys who were paising Google:
1. A search for conductive spray paint yields maybe 100k entries.
2. Overwhelmingly, conductive spray paint is an industrial/commercial product that has thousands of producers who sell and give info to industry types, not a consumer like me. (I learned a lot about the nature of this international industry.)
3. Those agents from these companies I reached on the landline were helpful, but yielded nothing for me.
4. My last resort was this GREAT newsgroup who I knew would come thru for me.

Thanks to all.

I'll only respond to this once instead of three times.

Why would anyone send a private email to someone and not include a valid return email address? Selecting "reply" and typing a nice return message seemed like a logical thing to do. I didn't ever suppose that the idiot sending the message was just sending spam. Now I know better.

I was just trying to save you the embarrassment of further public ridicule.

Alas, I failed.

First thing you need to worry about is which vintage of MSF it is.

Look at the model number, specifically the 3rd-6th characters (all letters). If they're "CLB," you will need the services of someone like Brinkley Electronics to program a new EPROM for your frequencies of choice.

If they're 'CXB,' you're better off in that the CXB series can be programmed with Motorola's MSF5000 RSS. Runs about $75 or so from Motorola, or there are folks (like me) who offer programming services. The kicker with that, of course, is that you would have to be local to me to get it done, and I don't think the '9' series calls show up anywhere near the Seattle region. ;-)

In addition to RSS, assuming your station is a CXB model, you will also need a 'RIB' (Radio Interface Box) and the appropriate cables. Lots of details along these (and other) lines may be had from the Batlabs site: http://www.batlabs.com

You may also want to look at: http://batboard.batlabs.com

The MSF5000 is a fine station. Enjoy it.

The U.S. uses VLH to "communicate with submerged submarines on at
frequencies of 3-30 kHz" (http://www.fas.org/nuke/guide/usa/c3i/vlf.htm).
The data rate is 50 baud but it must work - there are Trident ballistic
missile subs waiting for launch orders on the receiving end.
The depth and receiver characteristics are likely classified.

Hi Stï¿½phane,

Just so you don't confuse people you talk with, "stripline" is a line
sandwiched between two ground planes (could be air dielectric or
circuit board dielectric), but if it's a PC board with ground plane on
one side and a trace on the other, that's "microstrip."

I think 1.6mm thick fiberglass epoxy, with a 50 ohm microstrip line on
it at about 3mm line width, will handle 100 W at 450MHz just fine.

You can make a stripline or microstrip coupler that's shorter than 1/4
wave, and it should still have good directionality. It just won't
have as much coupling as it does at 1/4 wave. The coupling at 1/4,
3/4, 5/4, etc., is all the same, and there are nulls at DC, 1/2 wave,
2/2, 3/3, etc. The maxima are rather broad, rounded, and not sharp
peaks. I think I found a plot of the response on the web recently,
but perhaps I made it from formulas.

If you don't get it somewhere else, I can scan and send the ARRL
article on making an SWR meter using copper pipe fittings. I suppose
they are US-standard fittings, but there should be reasonable
equivalents in the civilized metric world.

Cheers,
Tom

If you had already searched with Google, or other search engines, it
should have been stated in the original message. Incomplete requests for
help just make it harder to help anyone.

There are other resources, like the EEM or Tomcat online databases of
products and manufacturers. Still it helps to know what someone has done
other than wring their hands and cry for help.

So that's the freq! For the life of me, I got zillions of hits, but none talked about the frequency. I only remember the old 1.8 MHz. (or whatever) Loran system.

787. Who had info on F-150 TSBs???

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-30 23:16:19 UTC
From: Scott <acepilot@bloomer.net>
Message-ID: <MxBSb.2841$tU6.4256@reggie.win.bright.net>
Source record: 29073

Had a major computer crash here last week. Somebody responded to my plea for help concerning noise in an F-150 that is killing my FT-857's HF ability. I lost everything since I had to reformat the hard drive and start over again.

Someone pointed me to a website that had a Technical Service Bulletin for fuel pump RFI. I'd like to get that again to print out. It doesn't appear that it (fuel pump) is an issue in my truck, but if there is a TSB for the noise, I'd like to make them do it under warranty. All I got today was "Good Luck!" from the Ford dealer. I took a book on RFI to show them possible causes and the guy kept saying the 2003 doesn't have spark plug wires so that can't be the source. Then I said it has a coil and they said, nope, each spark plug has its own coil attached right to the top of the plug. I concur, but there is a coil (in fact, 8 of them) and as long as there is, it must be generating high voltage to fire the plug, therefore, there is a primary circuit that tells the coil to fire. My contention is that any RFI generated by the spark plugs could be radiated back out of the coil through the primary circuit. The tech disagreed by stating that there is no primary circuit, that the coils are controlled by the computer directly. Duh. There is a wire connected from the coils to the computer. Sounds like an antenna to me. First thing they said was that my (cheap) radio doesn't have enough filtering on the DC power line. Bullshit! When the truck is off, it's quiet as a mouse. Start the truck and the noise starts. Popping goes up and down with engine speed. Noise blanker helps cut noise from S9 to S3, but I want better than that! If I disconnect the antenna from the radio with the truck running, noise goes to zero. So, you tell me that the noise is coming in through the DC power leads.

I asked if there was anybody I could contact direct at Ford...Nope. I guess Ford has no employees or engineers in Detroit. Model company...no wonder they can give away trucks...NO OVERHEAD!! Ya, right...

788. 30 meter beacon run this weekend

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-01-31 01:45:33 UTC
From: Tom Sevart <n2uhc@yahoo.nospam.com>
Message-ID: <bveptk$qbini$1@ID-52518.news.uni-berlin.de>
Source record: 29074

Hi all,

I'll be operating my 30 meter 100 mW CW beacon this weekend. The frequency will be 10.146 MHZ. Operating time will be on Saturday from early morning to about 2300Z. On Sunday from early morning to around 0300Z.

Details on the beacon are located at http://www.geocities.com/n2uhc_2/30m_bcn.html . Please send a reception report to me at n2uhc@yahoo.com. Please include your QTH, time you heard it, and how well you heard it. I'll respond with a QSL via email, or if you would like a paper copy please request one & include your address.

The antenna is a 30 meter dipole set up in an inverted-V style, with legs pointing N-S.

Thanks.

Hi Wes,

Not sure why it posted three times, wn has been having some trouble this
week.

Anyway, not everyone checks into usenet as often as regular email, so just a
courtesy
to reply to the group and individual. NOT SPAM.

The original post inquired about vhf amplifier designs on the net, I replied
with one link.
You provided several links too. Good.

If I should walk away a little smarter from something you or anyone else
posted that is a good
thing and nothing I should be embarrassed by.

Have a nice day.

jimbo

My 30 meter 100 mW beacon is running now on 10.146 MHZ. Antenna is a 30 meter inverted V. The beacon will be running until 1900Z tonight, then all day tomorrow until about 0300Z.

Please send reception reports to n2uhc@yahoo.com, please include UTC time you hear it and your location. Results to be posted later.

I used to use a 'slim jim' (2mtr version) for Marine VHF as well as 2mts,
worked very well indeed.

Make a 300ohm ribbon cable version and encapsulated in plastic pipe.

Can send you some building instructions if you don't have them already.

Tnx Michael for your suggestion. It was an oversight on my part about not mentioning prior searches on Google.

Secondly, I was seeking out help on this newsgroup. It is a great source because of the wealth of info and experience held by its subscribers. I was not wringing my hands in despair as you imply. I use this newsgroup as a fountain of hope. It is unwise to judge the emotional/psychological state of the sender from cold text.

See ya!

Disconnect the antenna wire and verify that it's shield is still well
grounded. The antenna end of the antenna wire must be well grounded to
the body AT THE ANTENNA end to minimize noise pickup.

Lots of times this connection is poor, either because of corrosion or
paint between the antenna body and the car body, or corrosion between
the antenna body and the coaxial shield. Either way it's a major
source of noise pickup.

Bob,
Take a trip to some of your local repair shops......
I know that at my shop that about once a month or two that I am filling up a pick up truck full of old and newer VCRs, DVDs, televisions, stereo equipment, CD players, CB radios, etc.and taking it all to the dump...... otherwise I wouldn't be able to walk around inside the shop.
I am in the Seattle area so it would not be worth the shipping costs.

You're in Seattle too? I might be willing to take a load of some fixable stuff at some point, however I have the same problem at home. Hate to throw anything away, but don't have space/time to fix everything.

Hey there Steve, and the group,

If you want some good reading on the operation of the 100khz Loran-C, download the manual for the rayplot 700L from Raymarine.com They cover the 'How it works' department real well. No schematics however. I have a small battery operated scuba tow unit good for bay, or lake use. It has no compass due to the very large motor magnets. I was thinking of building my small portable Loran-C receiver into a waterproof box, and towing an insulated antenna wire of perhaps 10 feet length behind me. But I was unsure how deep I could dive, and still have a useable signal. I have a 700L for land use in my mobile. It works great!

807. Re: simple synchronous detector?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-01 03:34:19 UTC
From: Y <zapary@hotmail.com>
Message-ID: <401C73BA.D2DDDC86@hotmail.com>
Source record: 29094

A regenerative synchronous detector can be built using a MC1330. A secondary coil is wound over the limiter coil and connected between the limiter output pin and ground through an emitter resistor. A .1 mfd capacitor is connected across the resistor. The secondary coil must be coupled and phased so that oscillation is possible. The MC1330 will lock to the incoming carrier. Coupling the secondary coil to the limiter coil is critical and requires experimentation. Jos! VE2 AUC

808. Best way to cut holes in aluminum panel? Label controls?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-01 04:46:26 UTC
From: Paul Clay <mrvansk@yahoo.com>
Message-ID: <401C84A2.D6A0ECBE@yahoo.com>
Source record: 29095

What's the best way/tool to cut or drill holes 1/8 inch to 5/16 inch in diameter in thin gauge aluminum (for inserting potentiometers and phono, power jacks, etc.)? I've tried using just a power drill and genernal purpose drill bits and the results have been sort of ragged (the edges of the hole are ragged and the process of drilling creates a depression surrounding the drilled hole).

What's a good technique for labeling front panel controls on a piece of homebrew gear? Are there self adhesive labels or decals that stick/wear really well?

Tnx!

Buy a good set of Greenlee punches - they'll cost a bundle but
there's no other good way to do it.

> What's a good technique for labeling front panel controls on a piece of

Go to a trophy shop and buy engraved phenolic plaque labels. They'll
cost ya about $2 each but look GOOD.

Get yourself a step bit. You just drill the starter hole, and then drill
with the step bit until you have the size hole you want. Much cheaper than
punches.

I use a tapered drill, it produces a very neat hole.

Print them on a sheet of paper, put that on the panel and cover it with
a sheet of plastic. You'll have to make holes for the controls, etc.

And to leave it to repair it with another set, mostly it's always the same
piece which is stuck.
So also here in The Netherlands, put it in the car and bring it to a guy who
always says, the people throw the money on the street, see what beatuful
expensive part are inside, I can use it later, even his house can't collapse
due to his "stock" hihihi.

Greetings Peter

You should include a low noise preamplifier in front of the receiver.
Due to the very high atmospheric noise levels on LF and MF bands, the
sensitivity for a typical receiver is very low (especially if a
ferrite rod antenna is used).

Below the surface, both the level of the wanted signal as well as the
atmospheric noise level will drop rapidly and sooner or later the
signal will be swamped by the receiver internal noise (high F figure).
A low noise preamplifier between the antenna and the receiver will
allow a weaker signal to be detected before being swamped by the
preamplifier internal noise when going deeper.

However, if the preamplifier is used close to the surface, it most
likely will overload the receiver, so a pressure switch should switch
out the preamplifier when you are (say less than 3-5 m from the
surface) on include the preamplifier into the receiver AGC loop.

Thanks to the group for all the past advice given on PCB
drafting software & UV exposure boxes, it's all being put to good use.

In the past I've used ferric chloride professionally as my
etchant (and left disposal of the etching solution to the work's
chemist) but now I'm doing things for myself safe disposal is going to
be my problem, searching on the web for an answer ammonium and sodium
persulphate come up as a suitable alternatives but not ones I've used.
Does anyone have experience of using persulphates as a D-I-Y PCB etchant
? Are they as good as ferric chloride, are there any problems with using
them & how easy is it to dispose of the spent solution ?

You can make a template of the front panel with a graphics program with hole locations, text, etc. Print them out on 8 1/2 by 11 inch label material. Cover the panel with a section of the same size plastic laminate, and you are all set.
I did a panel with this method 4 years ago, and the glue has not yet turned yellow.

I believe this is the site you're looking for:

http://www.arrl.org/tis/info/pdf/W1MG.pdf

Unfortunately that article is dated 2002, so your vehicle wouldn't be
covered.

You may want to try the following information:

Ford Motor Co
300 Renaissance Center
PO Box 43360
Detroit, MI 48243
USA

Tel: 800-392-3673 (all makes)
800-241-3673 (towing and dealer location service)
800-232-5952 (TDD)

Also from the original thread:

> Tell the dealer to look up Ford's technical service bulletin
> TSB 93-15-6 and/or TSB 95-11-3 (I believe the latter is an updated
> version of the former). This describes the problem, identifies the

I don't think I have ever seen a Greenlee punch for a hole that is only 1/8 of an inch in diameter. Most of the holes for the bolts I have seen are much bigger than that.

To drill small holes you can get or grind your own bits. They will have a point on them and be something like the spade wood bits. Also take a piece of scrap wood and put behind the aluminum.

A big question, but briefly.

1.Buy sheet metal drills - might be worth it if you are only looking
at 2-3 sizes.
2.With ordinary drills, use a backing board to stop the flared effect.
Start with a small size and work up in 64ths till you get the desired
size. Tedious, but works.
3.Buy a tapered reamer, and use it to widen a say, 0.25inch hole. Ream
from both sides, needs a bit of practice. Clean up edges with a bunny
knife.

For labels:-
1.The new DYMO labelling guns are good - much better than the old
embossed plastic ones - its a thermal printing sustem, works well.
2.Do your arwork on good quality paper to size, print it out, trim to
size, stick to front panel with clear self adhesice contact film. (Its
called "contact" here in VK, may be the same there, dont know.) A bit
of stuffing around, but worth it.
3. Buy a lettering template and draw directly on the aluminium with a
say 1mm overhead projector trnasparency pen. looks ok, then spray with
clear lacqer.

Dont be too hung up on what it looks like, it can get in the way of
actually getting a project on air - and besides, the person at the
other end of the QSO wont know anyway!.

There is only one good and safe way to do this.
Buy a Klein Unibit drill (there are other makes too) Step tapered from
1/8 inch to 1/2 inch. They do a nice clean job and the holes are always
round.
The tapered reamer is in my opinion an antique and looks like too much hard
work. Home Depot should have the Unibit.

A drill press will hold the drill much more steadily for cleaner
holes. Not always available, though.

There are various things which you can attach to a hand drill to get
much of that steadiness, kind of a ring plate with two rods that the
drill rides on. You could even clamp this on to your piece to get the
equivalant of drill press accuracy.

Marking the hole with a center punch is very helpful.

You will do better with a hand drill by using a pilot hole, then up to
the actual size you want. Step drills are another way to do this, and
work quite well.

An aluminum cutting fluid will help.

When drilling, patience is important. Let the drill speed do the work,
not the drill power or downward pressure. Forcing the drill will
create the raggedness.

You will also do better with specialty sheet metal drills, rather than
general purpose. Sharper is better. The TiN coated ones will stay
sharper longer.

For square holes, a metal nibbling tool is ideal.

As for labels, there are many types of clear labels which a laser
printer will print on, the inkjet ones can smear. Artist's fixative
spray will help.

Also look at things like the Brother P-Touch label maker, especially
the ones which attach to a PC.

That was the name of the step drill I was thinking of. Home Depot does
in fact have them, several versions with varying sizes. They also vary
as to material thickness capability (the rise between steps).

Very nice product. About $20-25 USD each.

>The tapered reamer is in my opinion an antique and looks like too much hard
>work. Home Depot should have the Unibit.
> 73 de Eskay.

This would work, but is hacky. With thin aluminum in particular, it is
very hard to get a good looking round hole with these.

If your time is worth more than minimum wage, it is very cost
effective to buy and use the right tool for the job.

If you have friends with similar tool needs, you can extend your range
of tools by borrowing back and forth.

Source record: 29009

Hi, I have the Kenwood TS-700A, 2m rig, I had a problem with the power cord, got bitten to pieces.
Does anyone know the proper pin requirement? Which of the four pins is to line up with the black, gnd and neutral? I am using it on 120v only but has the option for 220.
There are two horizontal pins, two vertical. Any help would be appreciated.

Thanks

I want to install a A99 antenna I was given by a friend. I have a 50 ft tower I want to put it on. Go to QRZ.COM, lookup my call sign (KI4CXZ) and you can see my mast. I really don't want to put this antenna at the top. About 3/4 way up. Is there anything to be concerned about how far to mount it out from the base. Thanks and "73"

Don't drill em, punch em.

Hand held squeeze punches are available everywhere. I also bought a
Greenlee 1/2 in punch; expensive, but it saved a lot of filing.

In the case of a LORAN receiver, over load is not a serious matter. The
receiver only has to decide
if a signal is there or not. The LORAN is a pulsed signal and you only
have to detect timing of the pulses.
If the receiver limits strong signals and does not lose sensitivity you
should be OK

Good luck

Since I have these power supplies laying around, I can't resist asking. :)

A friend is going to buy and/or build a robotic CNC setup for his plama
torch.
A system is $5000 complete or a mainboard and software can be purchased for
$1500
or so with him supplying the motors, power supply, etc.

He says he needs 35 volt power supply with 35 amps.

So if I wire together 12 power supplys (12v, 9a), voila, 36 volts at 36
amps.

Hehe, it can't be that easy can it?

No, it can't. The supplies are not isolated from the case, they are
not designed to be paralleled, the regulation tracks the +5 volt output
which usually requires a minimum load to operate. The 12 volt outputs
are low current, as well.

It's just as easy to dispose of as FeCl3. The solution doesn't keep very
well, unlike FeCl3.

The way it usually works is to send a three-letter group via VERY slow
CW on a VLF frequency, either via the land-based VLF stations or the
TACAMO aircraft (streaming a way-long wire antenna in flight). This
alerts the intended recipient to near the surface to raise the antenna,
or to float the buoy antenna, and pick up traffic via satellite burst
transmission.

What I usually do is take an ordinary screwdriver and slide a magnet over it
several times. After that screws won't fall off if you don't shake too hard.
Works well for me.

Last year, as an experiment, I marked up a small piece of double-sided copperclad with Sharpie and similar marking pens. I then etched it in a solution of sodium monopersulphate (cheaply available at pool-supply stores - it's used as an oxygen shock) and hot tap water. A plastic cup served as the container, and I agitated gently by hand.

It definitely etched! As I recall, 10-15 minutes was sufficient to etch the unprotected areas down to bare fiberglass. The etch was easy to monitor as the solution is clear to start with, and turns a clear blue-green as the copper is etched. The different marking pens I'd tried had different amounts of resistance to the etch... one or two stood up fairly well, the others did not.

I haven't tried actually making a functional board with this etchant yet, but may do so in the near future - I've refurbed an old HP flatbed plotter, and converted the pen-holder to use Staedtler (sp?) red-ink permanent marker pens which have a good reputation for etchant resistance. Some form of improved solution-heating and agitation/bubbling arrangment would probably be a good idea, to get a quick and consistent etch.

Disposal can be quite easy. Mix up a solution of sodium carbonate (washing soda, also sold at pool-supply stores as a mild alkali to raise the pH of pool water) and titrate it into the used solution. The dissolved copper will convert to copper carbonate, and precipitate out... copper carbonate isn't very soluble in water. Strain the solution through a paper filter (e.g. coffee filter) to separate the carbonate from the remaining solution (which should be clear once again if you added enough sodium carbonate).

I just dumped the copper-free solution into my swimming pool, and discarded the filter in the trash. If you want to really immobalize the copper carbonate, you could mix it into a batch of plaster-of-paris or portland cement and let it harden up, and then trash the resulting piece of rock.

For slotted head screws, I like the wedge type screwholders. They
work well, are easy to use, don't get in the way, and don't attract
undesirable swarf. I do not like magnetic tools for the latter reason.

I haven't found anything comparable for Philips head screws. I
actively detest the spring clip style screwholders since the spring
clips get in the way, and they aren't easy to use.

So since I always seem to have a bottle or two of expired Crazy
Glue, I will often just glue a Philips screw onto a screwdriver.
Since the goop is expired, it doesn't hold so well you can't easily
free the screwdriver from the screw, but it still bonds instantly,
so it is quick to use.

For holding nuts in sockets, a bit of modeling clay is just the trick.

Gary

Safe disposal of amateur quantities of ferric chloride is easy enough -
just solidify it in a small bag of cement.

>searching on the web for an answer ammonium and sodium

I haven't, but a friend has used ammonium persulphate and speaks very
well of it. He says it etches at least as well as ferric chloride, and
after use the remaining ammonium persulphate can be recrystallised out
of the copper sulphate solution.

But unfortunately he's in no position to demonstrate this any more,
because we haven't been able to find a source of small quantities (up to
a few kilos) in the UK. Apart from ferric chloride, and sodium
persulphate (which isn't as effective as the ammonium salt) it seems
impossible to buy small quantities of general chemicals, these days...
unless someone knows better... and I hope someone does...

The type shown here are the best. I was fortunate to get several
that have Phillips on one end and straight on the opposite end
about a foot long US military surplus.

Yes this is a good idea. Maybe not exactly what you are looking for, but its handy to have magnetized screwdriving tips for driving screws in all the hard to reach places without losing them. I just received a little magnetizer/demagnetizer gadget from rockler which works quite well.
Just have to remember to de-magnetize the tools if you are going to use them on electronic components :)
The magnetizer/demagnetizer can be found here http://tinyurl.com/2hnvr
It goes for $6.99.

An Old helo mech showed me some stuff called fuel lube. Aircraft Spruce P/N
09-25300. It is a very sticky grease and a small dab will hold the screw,
nut, washer whatever on the end of the tool. Even held a small nail on the
face of a hammer for one-handed out-of-reach nailing. It is also useful as a
gasket holder, anti-seize and other lube jobs. Not cheap, but I have had a
1# can for some time. "Guaranteed not to rip, rattle, run around the
seams, drip down your leg or smell bad in the summer time". I'ts better
than Dr. Chutes Two Root Rubbing compound.

For the stuff down in the power frequency range (under 100 Hz, not 100
KHZ) where the "bell ringer" systems operate, apparently SQUID (super
conducting quantum interference devices) antennas are used. See, e.g.,
http://techreports.larc.nasa.gov/ltrs/PDF/2003/tm/NASA-2003-tm212647.pdf

These SQUID antennas work up to a maximum of 1 KHz, so it's not going
to play for LORAN C.

845. 13.8 V power supply question

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-02 00:52:18 UTC
From: Uwe Langmesser <outhouse@midcoast.com>
Message-ID: <BC430972.B653%outhouse@midcoast.com>
Source record: 29036

I need a 12-14 V power supply for my new 2m tranceiver. On transmit I need probably 10 to 15 amps and I hooked up and old transformer with a rectifier and a filter section I get 15V at my filter with no load, the transformer is good for 25 amps) but if I draw 15 amps I will get too much ripple,

so I need a regulating section.

Homebrewing is called for.

Last years radio amateur handbook has a design for a 28 volt regulated power supply and while I would feel comfortable building a proven design I do not feel comfortable to redesign that regulating section for my needs.

So the question is does anyone have a diagram for a proven 12-14 Volt regulated supply for 10 to 25 amps??

Thanks for your help
Uwe

I have used the stuff under the name "honey grease" though it was
officially "grease, plug valve, hydrocarbon resistant.
Great stuff, until some doorknob spooges too much of it on a gasket and
gets it into a fuel or hydraulic system.

Cheers

I think I can get the frequency down to around 10.139 or .138 by adding a turn or two to the coil and changing capacitors. Before I run the beacon again, I'll do some experimenting.

I have a couple of these... they work great!

Only snag is stuff like the stainless screws they use around automotive
headlights...

Sometimes you have to fool around a little 'finding' which step of the
demagnetizer part works best for which driver. I've noticed if I don't
get a complete demagnetize using one step, it's better to remagnetize
before trying another step. Don't think the demagnetize is ever quite
100% either, but good enough not to pick much if any crud... a
de-gaussing coil is best...

My main objection to magnetic screwholders is that the screw is attracted to the edge of the hole, making it difficult to start it. Anyone else have this trouble?

I have used the kind with a flat rod that twists crosswise, the split bit that wedges over itself, CA glue, masking tape, grease, hemostats, and whatever else comes to hand. I can't say I have a favorite, but I agree that the double spring-clip type seems to get in the way, and often drops the screw at a crucial moment.

> Hehe, it can't be that easy can it?

Nope.

If you put three twelve volt power supplies in series the most that you can get out of them is the same as the lowest current rating of the three power supplies.

If you had three 12 volt 35 amp power supplies then you could do the 35 amp 36 volt setup, if you isolated the power supplies from ground and made some other modifications.

Try to find a dedicated power supply that is actually designed to the task at hand.

If you go to http://www.mods.dk and click on the Kenwood button it will show a frame on the left side of the screen. At the top is a button that is labeled manuals. Click on that and look up the manual for the TS-700 radio. It is presented as a pdf and should have the information that you need to make the power cord you need.

What electronic components are affected by using magnetic tools?
We used to have to take care around magnetic tape heads, but
unless you are working on tape (or cassette) recorders, I can't
think of any real danger of using magnetized tools?

The only thing affected by magnetism is magnetic media and heads. Nothing else will be damaged by normal magnets, though CRT's, compases and hall effect sensors will be interfered with.

Why's this being crossposted so so many random groups? I deleted the ones that definitly have no relevance.

In order to avoid the problems you have noted, find a thicker piece of scrap material. Make a sandwich with your aluminium panel as the filler. Clamp together solidly as near to the hole position as possible. Drill through the whole sandwich. It is the only way I know to drill neat holes in really thin panels.

If your panel is not that thin, say 1mm, drill a very small hole, say 1 mm using a PCB drill and open it out to the required size using a sequence of slightly larger drills and a reamer.

The best way is to use a hole punch. You don't find these very often. A QMAX type cutter is a good substitute but you have to drill a hole for the screw. Fortunately, the damage caused in drilling the screw hole is usually confined to the scrap "int' middl' t'ole".

J. Yazel:
This is not a phenomena unique to Seattle..... all repair shops everywhere have to deal with disposing of un-repaired and unclaimed electronics equipment. Most shops can only keep a limited amount of "bone yard" equipment to cannibalize...
.... and furthermore, it takes too much expensive labor time to search through old equipment for used and questionable quality parts when a brand new, unstressed part may be in stock or readily available..... Where ever you are, check with your local repair shops, the smaller independents may be easier to deal with.... most will gladly "donate" the scraps to you so they won't have to spend money to haul them to the dump.

A Punch is a good way if you are within about 2
inches of the edge...
Try a Whitney #5 punch. You can find the punch
kit and accessories here

http://www.newmantools.com/roper/5jr.htm

I've been using one of these for over 25 years.
They also last if you don't abuse them.

Hi.
I've read a very cool suggestion somewhere (GQRP's list perhaps) for
drilling clean holes in Altoids boxes (therefore all aluminium boxes):
fill the box with water, freeze it, then drill.

I usually start with 3mm bit for metal, then 4mm, 5mm and increasing in
small steps. Having a general purpose drill with linearly variable speed
helps too.

Cheap but somehow slow :-)

Go here and download the supply you need:

http://www.repeater-builder.com/rbtip/astron-index.html

The Astron supplies are well proven and the design is a very common one
similar for all regulatied supplies using the 723 chip.

I just took my friends word for it that that is what he needed. :)

Your response caused me to ask him for a few srpecifics. Turns out your instincts are correct.
Although still undecided, an example of a possible motor runs 4 amps at 2.8 volts.

He will be controlling the cutter in 3 axis.

Darn, thanks for straitening me out on how amperage cant be added together
like voltage.

Some good news is that each motor has a seperate power supply so the amps
needed are 9
or less.

He intends to use current set resisters. Somewhere my freind picked up this
advice:

"Before you start, you must have a suitable step motor, a DC power supply
suitable for the motor and a current set resistor. The motor's rated phase
current must be between 1A and 7A, or 0.3A to 2A for the low current range.
The power supply voltage must be between 4 times and 20 times the motor's
rated voltage. The current set resistor may be a 1/4 Watt, 5% part. Finally
have a STEP and DIRECTION pulse source available."

==========
Strong sigs can be limited simply by connecting 2 diodes (cross polarity)
across input of receiver.
Using general purpose Si-diodes limits V(peak) to approx 700 mV ,Schottky
diodes to approx 300 mV.

It can be easily improved. Eliminate the two .1 ohm emitter resistors
and connect one emitter to R6 and one to R7. Then replace R4 with a
pair of resistors, one going to R6 and one to R7, to average the
voltage from them to reproduce the current limit signal. You will
have to double the value so that two in parallel have the same total
effect. This change will not only eliminate two 10 watt resistors,
but will improve the current sharing between Q2 and Q3.

My only limiting factor(besides cost of course) is boom length - limit is 6m. I'm looking for a design for a 2m antenna that would maximise the gain. It should at least be able to handle 100w pep at the feedpoint.

> Get yourself a step bit. You just drill the starter hole, and then drill
> with the step bit until you have the size hole you want. Much cheaper than
> punches.
==========
I am getting good results with 2 sizes of tapered reamer
Initial hole drilled 1/8 inch.
Small diameter reamer from 3 to 13 mm (1/2 inch)
Larger diameter reamer from minimum 6 mm to 30 mm (approx 1.25 inch)

My reamers are Nipponese ,made by Futaba Tool Mfg. who produce 4 sizes ,of
which the 2 I use are size 1 and size 4

For larger holes (say for moving coil meters) I drill multiple holes ,
knock out and finish with half round file.
The latter takes some time obviously , if it is to be done neatly.

There seem to be a number of makers now. G&J Hall, England, make the Bradrad/Multicut series (available in either metric or fractional-inch steps) and the Conecut (smooth taper, available in both metric and inch :-)

Going back to an earlier comment, do think about buying a drill press - even a cheap import is so much better than a hand-held drill.

I have not seen any equations for a Pi network where you can enter the full complex number which would include the series resistance .

I know someone must have done it but it isn't in any of the ref-material

I have run across.

I did work out an equation some years back using APL2 which handles complex

numbers or complex arrays. I solved the network looking into both ends getting two equations.
rearrange both solving for the tuning cap. Then set up both equations making

one equal the other. Then arrange all those terms (about 15 on each side)

and solve for the loading cap. This will be a a quadratic equation.

Use the quadratic root (-B +/- squareroot (B*2 -4xAxC)) /2xA.

Now plug the values into the computer for load , inductor and Zin.

it should spit out the value of the loading cap.

It is a nasty process but someone has to do it.

I found out that if the inductor is too large negative restiance appears in the

output value for the loading cap. Also if all goes well the answer to the square root will be all resistive with no reactance.

Id post this however the terminal wont handle the APL characters.

Lots of luck

Art Young

Ferric chloride solution is somewhat acidic. If you add some baking soda, you will precipitate out almost all the iron. If you first use the solution till it doesn't etch well any longer, there's not a whole lot of ferric left in it; it's mostly ferrous, which isn't particularly corrosive. You can toss in a couple old steel nails to finish the conversion from ferric if you wish. Considering the amount of rust in junkyards, I wouldn't be concerned about the small amount of ferrous you're adding. HOWEVER, I would be more concerned with the copper ions, which, I believe, are considerably more toxic than iron to most life on earth, including things that digest sewage. If it's tiny hobby amounts, it may not be a significant increment, because of all the copper plumbing in homes, but to be safe you can lock it up in Portland cement as Ian says.

Another etchant to consider is cupric chloride. You can make a self-regenerating etchant; etching boards makes more etchant. Instructions at http://users.rcn.com/rexa/Projects/CuCl_ech.html.

Cheers,
Tom

What are you using for a transformer, and what are you using for a filter? If you've got a capacitor input filter with 15V no-load then I come out with a 10.5V transformer -- or do you have a choke-input filter?

In any case, your average linear regulator circuit wants the minimum voltage out of the filter to be 2 - 5V above the output voltage. With a capacitor input filter, and designing for reasonable peak current in the transformer and possible line sags this means that your transformer secondary voltage rating should be on the order of 18V (the circuit referred to by one of the other posters uses just this voltage).

With your 15V no-load filter output your regulator will have barely enough overhead to regulate the peaks; your ripple will still come through just shifted down by a couple of volts.

Just call around to shops or put an ad in the local classifieds, ham gear
will be a lot harder to come by than other consumer electronics because most
hams are fairly technically knolegeable people but you never know.

You might take seven identical power supplies, each capable of
delivering at least 35 A from the 5 V line and connect them in series.
However, you would have to disconnect the 0 V DC from chassis on each
unit, so that the chassis of each power supply can be connected to the
protective ground.

If these are ATX power supplies, you would have to look at the startup
sequence, if these power supplies do not go on-line, when the mains is
applies. This may require some optoisolators.

> sets?

For once in awhile use, a roll of masking tape does wonders. Tear off
a small chunk, poke your screw through it, tape it to the screwdriver.
Once the thing is started, tear off the tape. You can do the same
with nuts and nutdrivers. Not a production technique but handy
sometimes where you positively don't want to dismantle the object to
get a stray screw back. Even magnetic and clip types will lose a
screw if you bump them hard enough and sometimes the quarters are so
close that a magnetic tip will stick to the object more than to the
screw. For fishing stuff out, there's now rare-earth magnetic
grabbers with a high-powered LED in the center. Just ran across one
in the hardware store. I've used the wedge-fast slotted screw
starters and the Phillips screw starters, the masking tape beats them
both.

Check out Marlin P Jones (www.mpja.com). They have a number of surplus switching supplies -- they should have some 12V supplies that really _are_ 12, and are isolated so you can rope them up in series. I do not know if they have supplies that can go to 35 amps, but as you said in another post you can supply each motor seperately. I usually browse their site, then check out the supply manufacturer to see if the supply is still listed.

They _won't_ be as cheap as PC power supplies, but they _will_ give you a much greater chance of success, and the are cheaper than the same supplies new.

I'd say this is ok. Don't know how important. Haven't done a 723
regulator in a long time...

> You will
> have to double the value so that two in parallel have the same total
> effect. This change will not only eliminate two 10 watt resistors,
> but will improve the current sharing between Q2 and Q3....
> John Popelish

Remember. Cap input filters like this draw high peak current at the
peak of the sinewave when the caps get charged. It is not a sinewave
current waveform. Make sure that you have enough filter cap (& diode
capability) so that at the lowest point of the ripple on the filter caps you
still have voltage on the series pass transistors (the 3055's) which is
"enough" Here are some rough numbers, but should be close.
To figure how much drop you'll have with given caps or how much cap you
need to get a given drop you can use the formula I=C dV/dt where I is the
DC current (in amps), dVis the drop (in volts) you have room for over dt
which is about 7 miliseconds. Solve for C or V as appropriate.
The minimum cap voltage is somethign like 13.8 PLUS the drop across the
0.15s PLUS 2 volts for the darlington connected 3055's base and some left

over for collector voltage on the driver 3055. If I have it right that is: 13.8 + (7.5 x 0.15) + 2 (transistors 2 x Vbe) +2 (minimum driver Vcb) and this is at low line voltage.

I get around 13.8 + 1.2 + 2 + 2 = 19V. Oh yea, the transformer has to have 2V more to allow for the bridge diodes also. SO at 30-35 peak amps the xfmr needs to have 21 volts peak, if I did it right -- that's around 15V RMS (there is flatening of the peaks due to the peak current).

FYI:
On one I built, I wound a few extra turns on the transformer and added some diodes to provide the driver collector voltage. This was a 5V 30A supply and I was trying to minimize loss. When TTL was in vogue...

thin
> panels.

The extra sandwich material can be other aluminum OR hard wood,
dense fiber board, etc. Only trouble is that you can't see through to know
where you are drilling and must devise ways to line it up. A small pilot
hole in the top cover piece to line it up with a mark on the work.

The frozen water is a neat idea.

I have seen the uni-bit used on sheet metal ductwork & it makes clean holes,
but usually larger. Perhaps there are smaller ones.

HEY! Where do you get replacement thread-in tips for the old "automatic"
center punches, the spring loaded ones...slowly push until it pops ?

That is a very good idea. You can do something like that very cheaply
by just providing a small extra filter cap that is fed by two extra
diodes, to make a positive supply that doesn't have the full ripple
sag of the big caps.

I would build the thing with a 15 or 16 volt transformer instead of
the 18 volt one specified, unless you have lots of trouble with low
line voltage.

If you do use an 18 volt one, you can lower the peak currents and cool
the transformer, capacitors and output transistors off by putting a
big resistor in series with the transformer primary, such that at full
load you just barely have enough DC to keep the regulator
functioning. You still get the heat, but it is dumped into a
resistor, instead of those other components. It also reduces the
current thump when you turn the thing on and have to both charge the
caps and handle transformer core saturation.

I think you can also improve the load transient response by putting a
10 ohm resistor across the output transistors, base to emitter, and a
100 ohm resistor base to emitter on the driver transistor. I haven't
calculated the closed loop frequency response of this design.

Nobody's mentioned *nuts* yet. Here's my contribution on that part of
the problem:

For small nuts, say 2-56 through 10-32, just grab a length of 1/16"
diameter wire solder, lay its end across the flat of the nut and give it
a good squeeze with a pair of pliers. The solder will "flow" down into
the first thread of the nut and grab well enough so you can bend the
rest of the solder into whatever shape is required to put the nut where
it has to go.

Once the screw starts into the other side of the nut, a tug on the
solder releases it and you can usually get some sort of wrench or a
fingertip onto it for the rest of the tightening.

Use CuCl2 + HCl. After etching the Cu 2+ (cupric) ion goes to Cu 1+
(cuprous). Bubbling air thru it oxidizes the cuprous back to cupric [you'll
know when its done because the cupric is a bright emerald green]. Disposal is
easy -- you don't dispose of it, just reuse.
Do a Google search for CuCl2 and PWB etching and you can find more details.

Greetings!

I would like to know if anyone has been successful developing an interface for 3 wire serial feed to a PLL: (Clock, data, latch enable) using a PIC or similar devices. I presently use my computer to control my VFO. Software is the Code Loader from National.com It works very well. The speed of the Clock/Data appears to be high and I am wondering if a PIC could work at the same speed and/or produce the same rise time.!
If email is sent, please remove the xxx,

The series resistance of the inductor along with its reactance.

in that each entry is a full complex number one could enter any series

resistance associated with it say a tuning cap.

Yep, you are wrong. Insects had antenna millions of years before man
ever walked the earth. In fact, the word "antenna" comes directly
from the insect world and was adopted for RF antennas, because they
reminded someone of insect antenna.

>phono, power jacks, etc.)? I've tried using just a power drill and
>genernal purpose drill bits and the results have been sort of ragged
>(the edges of the hole are ragged and the process of drilling creates a
>depression surrounding the drilled hole).

If it really is thin gauge aluminum, then I'd suggest a hand-operated
reamer to enlarge a hold from about 3/16" pilot hole. Those are
in general purpose tool stores and can typically go up to 1/2" dia.

Also, it builds up the lower arm muscles... :-)

>What's a good technique for labeling front panel controls on a piece of
>homebrew gear? Are there self adhesive labels or decals that
>stick/wear really well?

There are still decals and press-on lettering kits in the electronics
stores but I prefer a better (but takes longer) process to insure that
normal fingering doesn't scratch or rub off the markings. Get some
1/16" thick (or thereabouts) plexiglass, lucite, even Lexan sheet
and use that for an overlay. The real markings can be done via PC
and inkjet or laser printer, black on white, or white on black, or even
with color. The clear cover sheet keeps the markings clean and
unblemished.

Takes some care to drill the acrylic sheet though, most need slower
speed cuttings and careful clamping to avoid fracturing when cutting
to size. Pilot-hole drill both the overlay and the front panel with the
overlay clamped onto the panel to insure good justification.

The nice thing about the synchronous serial interface is that the transmitter can clock data out at whatever speed it wants to -- so you can bit-bang with the PIC with no problem.

You may want to check if your flavor of PIC has an SPI port -- they're designed to implement just that kind of interface.

Source record: 28947

Wonderful, I might learn something here.
Here are some more details about the existing parts.

I use an existing center tapped transformer which gives twice 10.7 V. I also have 4 caps of 167 000mF at 7.5 V (which are currently hooked up for 15V max voltage) and two fat diodes. The transformer is probably good for 25 to 30A (it has a 3.5 X 4.5 X 6 inch core).

If the 15 V I get right now at my filter stage is barely enough for decent regulation I could double that (and also use a bridge rectifier) but then I would have to regulate that higher voltage down to the 13.8V I will most often use.

I looked at the design http://www.rason.org/Projects/powsupply/powsupply.htm that Tracy had suggested and it looks manageable to me (the Astron design someone suggested have additional windings on their transformers which I do not have on mine) but I do not have the expertise to change parts in the design to accommodate the higher voltage and current I could get out of my transformer. I am not sure if I only have to change the current limiting resisitor at the 723 as well as the resistors which determine the output voltage or if more elaborate changes involving the 2N3055's are necessary.

regards Uwe

My guess is that the plural for insect antennae came from Latin
and the plural for RF antennas came from a more modern language.
The word "antenna" entered the English language around 1646
from Middle Latin according to my dictionary. There were no
RF antennas in 1646, at least not on purpose.

This transformer is so close to the desired 13.8 volt output that I
would be tempted to use it unregulated. But you might want ot hang a
big 12 volt, 5 watt zener and a 10 ohm 2 watt resistor (in series)
across it to provide a minimum load. It will have some ripple
voltage, but it should do for most loads designed to operate from an
automotive charging system (which also has considerable variation).

If you want a regulated output, this transformer is not a very good
fit, unless you go with a switching regulator.

See the Atmel/Win32 multi-platform implementation of three-wire PLL programming at http://www.qsl.net/ke5fx/synth.html (direct link to the software at http://www.qsl.net/ke5fx/synth/synth100.zip).

It's in C++, which is not a problem for the higher-speed Atmel chips but might not be appropriate for a PIC.

For 1/4" hex screwdriver handles and bits http://www.brownells.com

Lifetime guarantee on the Brownells bits, they are replaced for free
it they break (shipped with your order for free, otherwise you pay the
postage).

For screw starters http://www.setools.com/sstarter.shtml

For the rest of it, a collection of 1/4" square drive extensions,
universal joints, and the like with a male 1/4" hex to male 1/4"
square adapter for the drive end and a 1/4" hex socket for the other
end. Also gender changers for the square to hex parts.

I have a collection of the spring loaded 8" to 10" long screw
starters, straight and Phillips, that were found at various industrial
surplus places. The link above will get you the same kind of tools
but the quality may be different. Mine are all refugees from the good
old days when things were Made In America and are either American or
Japanese made.

I have never had any problem with working around consumer level
electronics with screwdrivers with magnetized tips. I exercise a
reasonable caution and would not intentionally rest the tip on a IC or
component.

I keep a small super magnet stuck to the lid of one of metal tool
boxes and give many of my screwdrivers just enough strokes to pick up
the average screw when they have lost their magnetism.

When magnetizing screwdrivers, you have to start at one end and slide
the magnet off the other, then move it away and back to the starting
end for the next stroke. Using continuous contact and sliding it up
and down does not work well.

I use the Melabs PicBasic Pro compiler (www.melabs.com) and do the coding in Basic. It's really quite easy. With a 4MHz PIC and a software 'bit-banger' routine, I'm loading my SPI-based DDS chip about 166Kbs.

Hi David. I have a copy of the back issue of Break In with this transceiver in it + some follow up data. I have thought of modifying it for 40M also. Seems to be a better circuit than some other simple dsb ones I have looked at. I will look up coil data for L1 and let you know. Maybe this can be a joint project and bounce some ideas around? Cheers, Renfred ZL1BDL

Acquired about a dozen 8122 ceramic tetrodes (400 Watt dissipation, 500 Mhz max) pulls from a broadband EMC amplifier. I have no use for them other than trades or ebay.
Anyways, I'm thinking to test these things for emission I make a socket adaptor from the 8122 to something octal that my Hickock tube tester might deal with say a 6146 and test it as such. Won't know pass / fail but at least I can get an idea if they are all about the same results and weed out any duds.
Anyone ever try such ?

FYI: It was a 28 V supply when I started. I re-wound the secondary, I think
it was #10 wire, so a few extra turns of smaller wire (added to each end of
the secondary, as I recall) was a treat at the end.

This is interesting. I have to think about it. It'll slow the filter
cap charge time and lower and spread out the peak current.
T=RC and all that....

Your wavelength of interest is 3cm at a minimum...
you're trying to put them into a box smaller than
that.

How much gain should this antenna have? How
broad-banded does it have to be? How much
power does it have to handle? What kind of
polarization do I want? These are basic
questions you should answer.

From my point of view, a VFO completely independant of the personnal computer is desirable. This can be done with a PIC or other microprocessor with 2 thumbwheel switches for 99 channels (or frequencies) or a two digit display with up and down selection buttons. Ed!

Unclad perf-board is generally used for wire-wrap applications only. To do wire-wrap work you need a wire-wrap tool and a roll of wire-wrap wire. Both are available at Radio Shack. You buy the type of IC sockets that have long wire-wrap pins. For leaded components, you either wrap directly to the leads or you put them in wire-wrap sockets.

Wire-wrap works OK for digital and low-freq analog work, but it doesn't work at all for SMT parts. You generally need a good copper ground plane for RF work.

Thanks... but one more question.. The boards I've seen have individual
copper pads that surround each hole. The pads do NOT interconnect holes.

If these are for wirewrap, why the copper pads at each hole?

- jim

p.s. I'm familiar with many fabrication techniques, I'm just trying to
figure out how one works with these particular boards.. i.e. why are
these boards so common and electronics stores.

I don't know what the manufacturer is thinking when they do that, but I find the solder pads very convenient for mechanically holding the componants to the board. With just wire wrap things slide around (and it didn't occur to me until _just now_ that I could have used glue).

I generally prefer dead-bug on a ground plane, or paying a few bucks to a quick-turn PCB house.

Well, this is the second newsgroup where no one has told you how to test
them but has offered to buy them instead, so let me suggest a procedure:

- Sell the tubes to Gregg at a high percentage of the "tested" price.
- Promise to take back the bad ones.
- Count how many come back.

That's the usual way. If you just show people the front of the board it
doesn't matter if the back is untidy.

My name is Onno de Vries and i'm living in the Netherland and building
big amps is my hobby.
I just bought a 4CX 5000A on a radio market here for a good price (180
Euro) including socket.
Becourse the price was so good i took the challenge to build a 88-108
Mhz final from it.
After some experimenting i found out that the anode resonator a a bit
of a problem course of the high cappacity of the tube.
I try to do it with a double output coil (together Almost a half wave)
wich you see in manny designs for 144 Mhz amateur amps using for
example the russian tube GU84.
This works but it has a terrible efficiency,about 25%.
I hope that somebody can give me some Info about making a good and
high efficiend tank with this kind of tube.

Greetings.....Onno

It is often done with wire on the backside of the
board.
Sometimes the perforated ground and power strips
from vector are used.
If there are a lot of connections, wiring is done
on the top, fed through and soldered on the back.
Wire can be grouped into routing channels and tied
to the board. (I use 4 pound Monofilament as a
tie.)

Vector board is not suitable for RF except for
very simple circuits.

Hello-

I am looking for somebody to build a K2 (Elecraft) for me.

Can anybody recommend a good quality builder with plenty of test equipment
and experience?

Or if anybody in this ng builds K2's, please let me know.

Thanks and 73,

Joseph AJ1J

Perfboard was around long before most hobbyists had heard of wire wrap.

Once transistors came along, perfboard tended to be the method of
construction, unless you were planning to do it point to point on
a chassis like you would with tubes. "Messy" has no relevance since
the wiring was under the board. You'd use component leads to connect
the parts, and if they weren't long enough, bits of wire. And the ones
with bits of copper at each hole had the advantage, as someone pointed
out, that you could solder the components to the board before adding
the wires.

People were hesitant to make their own etched circuit boards, and even
after they became fairly common in hobby circles, many would say "I don't
want to bother" and they'd stick with perfboard.

If perfboard faded from view in recent years, it's likely because
etched circuit boards have tended to take over, if not made by the hands
of the hobbyist then because people were buying premade circuit boards.

As someone pointed out, perfboard is not so great for RF. Better
to use a blank piece of copper circuit board, and build on top of
that, so you have the copper as a good ground point. But that's
likely "messier" than using perfboard with the wiring on the bottom.
But how something looks is irrelevant. You can stick it in a box
out of view. Building over circuit board actually works better than
perfboard, because it's easier to run wires in a three dimensional
space.

Of course, from time to time I've used copper circuit board
as "perfboard", drilling holes where needed and reaming out the copper
from around the holes so the components go in without shorting. Wire
up on the non-copper side of the board, like perfboard, but all
ground connections go to the copper on the top side.

941. 433MHz tracker

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-04 19:19:25 UTC
From: stanandsue2000REMOVE@REMOVEyahoo.com
Message-ID: <4021432d.16891410@news.compuserve.com>
Source record: 28977

hello folks , hope someone can help me

i have built some 433MHz CW transmitters and used them for tracking model airplanes and stuff so I can find them if they get lost , the only ones i have built so far are only a couple of mW output , the company make they low power modules say no license is required for their use

ok , so now i want to build a higher power one for greater distance , thinking of using the linx modules which can either have 10mW or 50mW output at 433MHz CW

my questions

1) as power increases at some point i will need to get a technician class license , no problem as i will do that , but my question is at what power level is this required ? can you point me to where this is defined ?

2) i know building little transmitters for sale as a product requires an FCC registration number ... but building only a couple for your own use does not .. correct ? (if so hams couldn't ever build their own transmitters)

thanks for any assistance ... stan

Yes I agree. I suppose I should have said.. I've seen SOME sloppy work. IF one takes their time, they could do a neater job (trimming leads and touching with solder, not globs and such) and even then enclose it to make it look a bit more attractive. MNS

I think there's a lot of technically illegal radio building that's tolerated because it's not bothering anyone. Building your own 2mW transmitter and using it for fun is a lot like driving at 90mph on a deserted freeway -- they're both illegal, but if you do it well the law will look the other way. This is how we all got away with those AM transmitters on our RatShack 100-in-1 project kits when we were kids.

Building your own transmitters that are within the rules for unlicensed use is technically illegal but practically OK (see above). Amatuer operators are allowed to use our own equipment because we're presumed to know what we're doing by virtue of having passed the test for the license, and because the gov'ment knows that we're self-policed and will try to get violators to shape up on our own before anyone calls the FCC.

By all means go ahead and get a licence -- then you can not only dink with building a better beacon, but you can fly on 50MHz and (a) always have a frequency to yourself and (b) confuse everyone with your single-digit frequency flag.

If you do this then technically (there's that word again!) you'll have to rig the beacon up to send your call sign automatically at least every 10 minutes, but aside from the 100W power output this would be a good way of distinguishing _your_ beacon from everyone else's. You may be able to get away with putting a placard with your call sign on the aircraft, but I think that rule only covers the transmitter with which you're flying the plane.

Assuming you're in the U.S., you need a copy of Part 15 of the FCC rules, which deals with unlicensed transmitters among other things. I imagine it's on the web these days -- if not, it's available from the government printing office for a nominal charge.

And the US government will refer to it as "Part 15 of CFR 47" -- CFR 47 being volume 47 of the code of federal regulations. If you get if from the gov'ment as a book it will come bound with other parts -- my 1992 set of CFR 47 has three volumes.

A good way to connect the components is to simply bend the component leads over. Often, they're long enough to reach between connected components. If not, short bare wires can be added. It can be done quite neatly, and the result is very durable. But if beauty is important to you, you should probably go to the trouble of making a PCB.

This method shares a problem with conventional one- or two-sided non-ground plane PCBs in that proper bypassing and "grounding" requires some skill and knowledge. It's easy to end up with "ground" currents from multiple circuits sharing a common conductor, which can often lead to crosstalk and oscillation. This becomes more of a problem with increasing frequency, but because virtually all modern semiconductors have substantial gain at very high frequencies, it can still be a problem even when the operating frequency is low. I personally favor "ugly" construction, in which components are mounted over a solid ground plane. This reduces the impedance of inter-circuit ground connections so is considerably more forgiving of less-than-optimum layout.

The information you want is almost certainly in Title 47 of the Code
of Federal Regulations, Part 15. "This part sets out the regulations
under which an intentional, unintentional, or incidental radiator may
be operated without an individual license. It also contains the
technical specifications, administrative requirements and other
conditions relating to the marketing of part 15 devices."

http://www.access.gpo.gov/nara/cfr/waisidx_02/47cfr15_02.html

Take a look at section 15.209, which covers radiated emission limits
for "intentional" radiators. The limits are not defined in terms of
transmitter power, but in terms of the field strength at a specific
distance and frequency... this takes antenna gain into account.

In general, I'd guess that if you buy one of the little commercial
modules which is intended for Part 15 operation, and use it with the
sort of antenna that they recommend, you'd be safely within the
emission limits. If you add a gain antenna, or an outboard power
amplifier, you'll need to simulate and/or test to make sure that you
aren't exceeding the specified limits.

>2) i know building little transmitters for sale as a product requires
>an FCC registration number ... but building only a couple for your own
>use does not .. correct ? (if so hams couldn't ever build their own
>transmitters)

Several different sets of rules apply here, depending on whether
you're going to be justifying your use of the device under Part 15
(license-free) or Part 97 (Amateur Radio service).

For Part 15 operation:

Sec. 15.23 Home-built devices.

(a) Equipment authorization is not required for devices that are
not marketed, are not constructed from a kit, and are built in
quantities of five or less for personal use.

(b) It is recognized that the individual builder of home-built
equipment may not possess the means to perform the measurements

for determining compliance with the regulations. In this case, the builder is expected to employ good engineering practices to meet the specified technical standards to the greatest extent practicable. The provisions of Sec. 15.5 apply to this equipment.

For Part 97 (Amateur Radio): in general, it is _not_ necessary to have an FCC registration or certification to build or sell radio equipment intended for use in the Amateur Radio bands. In this case, the responsibility for the technical correctness of the equipment belongs to the amateur-radio operator who actually uses it, and not to the builder/seller. Amateur Radio is specifically designed as a service intended to support experimentation.

There are some exceptions, having mostly to do with high-power amplifiers and with equipment which could be used both on amateur bands and other bands (which generally _do_ require certification).

Actually, as I read it, if you homebrew a system which stays within
the FCC Part 15 limits, it's perfectly legal. The rules have a
specific "no certification required" exception for systems which are
built for home use, not-from-a-kit, in small quantities.

That's right...

Maybe it would help to give an example where plain perfboard was the best construction method. I recently built a small power distribution board which involved four 0.1in-pitch connector headers, a voltage regulator IC and a few passive components.

Why choose plain perfboard for this project? Mostly because the wiring underneath was going to be fairly complex, so hand-wiring was going to be the easiest way to make the board reasonably small. The advantage of hand-wiring is that you can have as many crossovers as you like, using insulated wire.

What other techniques didn't I choose? Even a double-sided PC board would have needed some jumpers, and wouldn't have been worth the effort for a one-off project. A single-sided PC board would have required lots of jumpers, and copper-strip perfboard (Veroboard/Vectorboard) would have been even worse.

So bare perfboard it was. The four headers were temporarily superglued onto the board, so they wouldn't fall out when the board was turned over to do the wiring. Under the board, I ran a common ground bus of 18SWG/16AWG tinned copper wire around all the headers. The other small components were pushed through the holes, and anchored by their leads as the various connections were made.

Most of the wiring was done point-to-point using the bare component leads. Crossovers were handled using kynar insulated wire - sold for wire-wrapping, but excellent for point-to-point soldered wiring too. By the time all the header pins had been soldered to, the headers were well anchored through the board and are very secure.

The whole thing looks quite tidy from the top. If neatness is important (and indeed, why not make a good job of it?) the main consideration is to cut the board cleanly and file off the ragged edges.

Certainly... and as I just said, it's one of the preferred techniques
for one-off construction.

>If perfboard faded from view in recent years, it's likely because
>etched circuit boards have tended to take over, if not made by the
>hands of the hobbyist then because people were buying premade circuit

>
Maybe plain perfboard just hasn't had much publicity. As an author, I
can see why: if it's a fairly basic 'follow these instructions' project,
then at the very least you're expected to design a PC board; but if it's
a project for experienced constructors, you don't need to tell them how
to build it. In either kind of article, plain perfboard probably doesn't
get a mention... but it's still there.

>As someone pointed out, perfboard is not so great for RF. Better to
>use a blank piece of copper circuit board, and build on top of that, so

Yep. The strengths of plain perfboard are for DC, audio and slow logic
circuits, and in the sheer versatility of hand-wiring underneath the
board.

>But that's likely "messier" than using perfboard with the wiring on the

>

If all the grounds are to the common top-side groundplane, it doesn't
look messy at all. The top-side looks very neat and the wiring
underneath is simplified by the absence of ground wires. Above all, the
RF performance will probably be very good.

For this kind of project, I very often use PCB design software to work
up the layout, but don't always etch a board. Just as often, I cut a
piece of single-sided board, tape a 1:1 printout of the PCB design onto
the board and use it as a drilling template. Then I hand-wire the
underside using the layout as a guide.

If you look at the manhattan style work of Jim Kortge
(http://www.qsl.net/k8iqy/) or Chuck Adams (http://www.qsl.net/k7qo/) it's
hard to call it "messier".

Of course, few of us mortals can do the sort of work they can.

While encoders can be found for upwards of fifty bucks, plenty of encoders that do a much nicer job than thumbwheel switches cost barely more than two. And why would you use a two digit display when a nice 8 digit LCD can be had for around five bucks, less if you're willing to hunt around. This stuff may have made sense when it was all going to be lashed together with 7400 series logic chips, but with a PIC or other processor, the encoder and LCD display is a lot easier, and usually cheaper, to say nothing of nicer.

I just posted "CrystalCalc" to the Downloads section of my web site (http://mysite.verizon.net/jdrocci/).

This nifty little Windows program calculates all the important motional parameters of a quartz crystal with information derived from a few simple measurements. Those of you who are designing crystal ladder filters per the Hayward (W7ZOI) or Hardcastle (G3JIR) methods might find this very useful.

This is first-cut code. I'd appreciate feedback.

Roy,

It has been a while since I read it, but isn't the bulk of the requirement a field strength number? I run a validation department and we measure field strength for our products. If there is a section of part 15 which gets specific (like I think the old 136 KHz part or the AM band where a power and antenna IS specified, then he's ok. Otherwise he'll have to measure field strength.

Cross-posted to: rec.antiques.radio+phono,rec.radio.amateur.boatanchors,rec.radio.amateur.homebrew,sci.electronics.repair

I've got one of my Hickok LS 15874 L2 Cardmatics going. I cleaned, lubed and realigned the switch matrix as well as other switches and also found a cold solder joint from a previous repair. About 100 of the switch matrix pins had what looked like old paper capacitor wax on them, very sticky! I took all the pins out, cleaned each one and the sockets. (An ultrasonic cleaner would have been nice.) It took several attempts to get the clearance correct, since the jam nut moved but I finally figured out a system. Now it appears to test tubes just fine but it still has one problem that escapes me and wonder if anyone would have any ideas. It responds per the manual to all test cards except card 9, Gm, Low Ib. About half the time card 9 will kick power off and I'm guessing it's because the meter kicks backwards below zero when button 2 is pressed When it doesn't I can adjust Low Ib per the manual and seems to work fine. However sometimes the meter needle doesn't go below zero enough to kick the power out but when this happens the Ib control has no effect! Any ides or tips appreciated.

Ian, I'm in perfect agreement with what you and Michael Black wrote.

I base that on working prototypes made for over three decades. It
seems as though perfboard has been around longer...:-)

One thing that all should remember: Electrons don't care about "neat"
construction. "Neat" gets something past inspectors, appeals to
customers, looks mighty fine and "professional" in photographs.
Electrons don't care for any of that. Fields and waves only care about
placement of conductors and nearby dielectric material.

>> And the ones with bits of copper at each hole had the advantage, as
>>someone pointed out, that you could solder the components to the board
>>before adding the wires.
>>
>>People were hesitant to make their own etched circuit boards, and even

>>don't want to bother" and they'd stick with perfboard.

Perf and hand wiring SAVES TIME. Homebrewing is about making
electronic things at home. Few of us have TIME at our disposal.

For relatively simple circuit arrangements, it would take me (somewhat
experienced) more time to sketch out a PCB foil pattern and check it
against a schematic than direct-wiring a perf-board circuit. A PCB
still has to be masked and etched and cleaned.

Printed circuit boards originally were a tremendous advantage in mass
production of electronics. It could physically hold components as well
as perfectly reproduce wiring paths...compared to the longer time needed
to mount (vacuum tube style) components and then hand-wire all the
connections, usually in several stages of wiring by different assemblers.
Production costs dropped considerably once all got through the
capital equipment expenditure for PCB machinery.

SMT got a big following because it was small...but also because it
cut down on production even more. Fewer holes to drill (sometimes
none) and the "baking" ovens didn't need as much maintenance as
the flow soldering machines did with peanut oil, cleaner and degreaser,
solder solutions. SMT took the basic PCB construction technique.

>Certainly... and as I just said, it's one of the preferred techniques

Perf with hand-wired "solder side" connections doesn't photograph
well. Image is important in magazine layout. :-)

>
>Yep. The strengths of plain perfboard are for DC, audio and slow logic
>circuits, and in the sheer versatility of hand-wiring underneath the
>board.

Right on! But...if one is familiar with RF layout through experience
and a "feel" for lead placement and lengths, perf can be used on
up to 70 MHz. That is NOT recommended for beginners who have
just memorized Ohm's Law.

At RCA EASD in the 1970s we regularly used Douglas Electronics
11-DE-1 boards for prototyping digital logic at equivalent clock rates
up to 10 MHz. Those held 12 DIPs had three-hole pads and #24 or
#26 insulated wire did the interconnects on the component side. A
44-pin edge contact allowed plug-in assembly and extenders. That
was most excellent for churning out 1- to 3-of-a-kind prototypes at up
to 150 cards per system. Techs could just follow a schematic and
hand-wire the cards...sort of "connect the dots" kind of operation.
Was very good with few errors done by anyone.

Douglas is still in business and the 11-DE-1 prototype board is still
available in the USA at about $12 each. A comparable Vector
Electronics prototype board is about the same price. I prefer the
Douglas since it is gold-flashed and a variant is available with a
ground plane on the component side.

I cheat a bit. Originally an illustrator, I sketch out the foil paths on
vellum 1:1, mark the drill holes and use the vellum as a small
center-punch guide. The paths are then painted in with lacquer,
free-hand, using the vellum as a guide. Lacquer can be peeled off
after etching with a sharp graphics knife (an X-Acto modeller's knife
to olde-tymers) and dissolved in acetone to be reused later.

Lacquer works fine with ferric chloride etchant. Enamel does NOT.
Enamels, now common in aircraft model shops can be undercut in
the etching. One has to really hunt for low-enough-price lacquer
now but it once was standard "dope" for modelers. I'm still using
a half-pint bottle of Testor's model airplane Dope obtained in 1947
(Testor's wisely changed the name slightly after that). Acetone in
pint can sizes is available in U.S. do-it-yourself stores. :-)

Yes, virtually all the part 15 specifications are field strength.
However, if the power is known, the field strength can often be
approximated by modeling or by making some assumptions about antenna
gain and efficiency. Accurate measurement of field strength isn't trivial.

I am trying to build rf transmitter and receiver that could transfer information (doors open closed, light on, etc, etc) from my car in the parking lot to my office desk. The distance is about 100m. I would like to have the receiver to be very small-key chain size. Therefore I thought high frequency might result in a smaller antenna. Most probably bandwidth will be very small (I do not need high speed data transfer). I am not sure about the polarization issue. About the power, that depends on the design, most probably. I am planning to use the IC from; http://www.maxim-ic.com/Wireless.cfm

Is it possible to do this kind of a device that small?

Easily... as long as all it has to do is receive. You
can pump out 20W of UHF RF from your car, you'll
hear it without any antenna at all inside, probably.
Your concerns are path loss (not that much through
the walls of the building) and receiver antenna
inefficiency (the greater of the two, since you put
a small size limit).

Perhaps you're talking about this chip:

http://www.maxim-ic.com/view_press_release.cfm/release_id/932

Pretty impressive, I must say... looks like fun.

Keeping this On Topic for r.r.a.a, I'd start with
a piece of wire 1/4 wave long, run around the
perimeter of your device, as an antenna.

Hey all,

My current I.F. bandwidth is 8mhz at the 6db points. I am looking at pulses of .8microseconds length, or about 1.25mhz. If all else remains the same, and I change the swamping resistors, and tweak the slugs for a 1.5mhz I.F. bandwidth at the 6db points, what increase in signal to noise ratio should I see?

I don't have a catalog anymore, but Vector used to make a variety of
pins, for both wire wrap and solder, that fit in their perfboards.
Punch in the pins, mount the components on them, run the connections
on the bottom and solder. They also had a wiring pencil that could be
used to run the connections. The wire had an insulation that would
melt when hit with solder. I wired up a couple of simple IC based
digital designs with one. I just used normal DIP sockets for the IC's.

I'm using a very elegant "in-between" technique which combines the
flexibility of perfboard wire with the shielding and relative precision
advantages of copper-clad.

It's also very cheap!

I buy rolls of adhesive copper tape of various widths from a stained-glass
supplies store. I'll use the wide tape for covering one side of the PCB
with the ground plane. Then, on the other side, I'll construct traces of
the
size and placement that I want with small pieces of copper tape.

If I need to make a correction, I can usually add or cut away more foil.
If I need to join pieces of tape electrically, a small dab of solder along
the edge works nicely.

Copper tape allows me to do double sided work at will without the
need for chemicals or the danger of using an electric drill to rout away
copper.

I've been able to bang out one small circuit per weekend and usually get
it right the first time, if not the second.

Try it! You'll be pleasantly surprised.

The Eternal Squire

Try placing the output of your crystal filter through a capacitive divider
back to the input. You'll get plenty of feedback that way! :)

Is this an exam question?

If "tweaking" the slugs for a more than six times reduction in bandwidth doesn't break anything your signal/noise should go up by around 8dB -- you'll lose than 8dB of noise, but you'll also lose a bit of the signal's sidebands.

Your pulses will be way distorted, though.

Did I pass?

Hey Tom,

Well, I've downloaded RFsim99 which allow to compute some microstrip or striplines couplers.
Unfortunately, all parameters are not taken into account line frequency or power.

I would appreciate if you could send me the scan of the mentionned pages.
Here is my mail : stephane.rey@netcourrier.com

The link from Wim seems very interresting to. I've to investigate more.

Thanks a lot for your support.

I told you if you moved those jam nuts at the bottom of the reader
you'd have fun! Have you replaced ALL of the electrolytic caps? Caps
could be the cause of what you are seeing. Plus--seems like there is
also an adjustment for the sensitivity of the circuit breaker in the
machine. There are something like 50+ cards to calibrate the
machine--went through all of those?

==========
Double sided copperclad board is a universal base for anything electronics including RF circuits.
I prefer the already mentioned 'dead bug' or 'ugly construction ' method where ICs are involved (legs up), with the legs to be earthed bent down and directly soldered to the board.
Earthed components serve as connection posts for other non-earthed circuit components. For connecting points free from earth I use a special 'island drill' ,a cylindric rotary bit covered with 'diamond grit' leaving a insulated 5mm diameter island to which up to 4 components can be joined.
Instead of the islands I also use small 0.25 Watt , 10 MOhm resistors with one end connected to ground ,the other end serving as post ,since many circuits have impedences 2 orders of magnitude lower than 10 MOhm.

All earthed components are soldered to other side of board via drilled holes ,hence are perpendicular to board face.

The 2 copper clad sides are joined either by multiple connections through drilled holes ,or all-around board edge copper wire/strip connection, the latter especially for vhf circuits.
I have no experience in UHF/microwave home brewing , but understand that single sided copper clad teflon board (thin) is normally used.

As far as superglue is concerned a warning !

Superglue is Cyanoacrylate , which if heated releases a very nasty gas which
really 'hits' you when inhaled.

Recently I superglued a component before doing some additional soldering
work around that component.
I now know I shall NEVER do that again.
Superglue is fine but not in a environment involving heat at soldering
level.

I'm aware of that problem, but in the application I was suggesting, the
amount of superglue that can get heated by soldering is trivial.

There's no problem unless you are already inhaling flux fumes... so
"don't inhale."

Source record: 28864

I have ALWAYS used plain (no copper) perfboard for my digital circuits. It's point to point wiring but I don't leave the wiring on the underside of the board, I route it around on the upper side. I prefer this method because I find it looks nicer, and it gives easier access to the bottom of the board for soldering modifications, repairs etc. Overall I have found it provides a very reliable and compact construction.

I'm not entirely sure why I started building this way. My first big digital project started when I was aged 13 (http://www.hanssummers.com/electronics/clocks/sidereal/intro.htm) and this would've been when I first used the method. I didn't have any "mentor" to follow on digital circuit construction, I just came up with this method as the best available for what my resources were at the time, and have stuck with it ever since. I still believe it's the most appropriate for my circumstances (VERY limited hobby time etc).

There are many examples on my website (all my projects use this method), some good pictures to start with are at:

http://www.hanssummers.com/computers/newz80/intro.htm
http://www.hanssummers.com/electronics/equipment/spectrumanalyser2/index.htm

For RF work I tend to use "ugly", i.e. a groundplane PCB with the components anchored above. If extra mechanical stability is required at some points I use a very high value resistor or very tiny value capacitor (depending on what the circuit will allow without alteration of its performance).

I have never used a PCB, for several reasons, not least because as Len said, it can take longer to design and fabricate a PCB than to handwire a perfboard. The main reason for me is that a perfboard is easy to modify, a PCB isn't. This is useful when a design is finished if some modifications are required, but most importantly in my case it's vital because I never completely design a circuit before I begin constructing it, I just have a bare bones design in my head then start building it and design the finer details as I go.

Wish I knew how to pass on that "feel" for RF layout to other people.
It's easy to explain to someone why their existing layout doesn't work,
but more difficult to make positive recommendations so their next
attempt *will* work.

I once wrote an article about that for RadCom, which was lifted by the
ARRL Handbook and survived for some years as part of the Construction
chapter as 'From Schematic to Working Circuit'. That chapter, taken as a
whole, is a pretty good basic reference.

But in the end, there's no substitute for your own experience. Just
build and build and build. Notice what works, and what doesn't... and
then the trick is to understand why.

The lack of those paper-graphics skills is why I use the PCB software.
Heck, I even use it for roughing-out stripboard layouts, to try to
maximize the use of the strips.

In Europe there's a gadget called a Dalo resist pen which is made
specifically for hand-drawing on PCBs. It has a fine fibre tip and very

thick, quick-drying ink. It's very expensive for what it is (namely a not very good fibre-tip pen) but with care it can be quite effective.

As many people already know, the Staedtler marker pens (waterproof/ wasserfest grade) are excellent for touching-up photo and iron-on resist patterns, but they're not as good as the Dalo for filling large areas.

hi,

I know you want to make your own.

If you want a set of us gov military surplus leads with all the
connections
you'll ever need just do a ebay search for test lead military

you'll find a nice new set arout 7 bucks or so (don't pay more!)
universal test lead set by elwyn industries.

Chris
I am guilty of not heeding your advice on the jam nut but it was not intentional mistake, it was the result of several attempts to get the parts back together. But a dope slap imigh tbe in order. I'm very impressed with engineering, design, and manufacture of the switch. Except for alignment, I don't see any need for improvements. I'd guess the facctory had a jig for aligment. I used a 13/64" allen wrench as a "feeler guage" after I determined what clearance was necessary to make sure all pins were out and how much they needed to go down so the female contacts would snap in the grooves of the pins. It took hours but the next time it will be quicker!
As far as the 54 test cards, I can't get proper readings on 1 thru 5 as my Cal. Cell is dead, or Card 9 but the rest are in spec! For the calibration cell Alan Douglas's book shows a 4.7 volt Zener while the USM-118 website has a 5.1 volt Zener and I'm trying to find out if the difference is important.. I think I may attempt to recharge the Cal. Cell mercury battery with my constant current source and see what happens.
The tube socket voltage and resistance readings pretty much agree with the data in the manual. All the electrolytics pass on my Dick Smith ESR meter.. I'm a rifleman not a shotgunner when it come to caps unless there is evidence that most of the caps are suxpect because of manufacturer or age. Besides, I like to know what component caused the fault. Next I think I'll let the unit hot soak for 24 hours and look at it with a scope.
It passes the breaker tests fine so I don't think relay needs adjustment. Since the Card 9 problem is not always repeatable it's difficult to pinpoint. What happens on Card 9 is sometimes the meter tries to go below zero and sometimes it kicks the unit off. I'm still trying to figure out how this Gm balance bridge circuit works. I've colored a set of schematics with Card 9 switches activiated and trying to get thru the maze to see if I can pinpoint the fault.
All that being said the Cardmatic is one hell of a design for a tube checker! I've got to get it going because I hve hundreds of tubes to check!
Any all tips appreciated.

Don't! At best, it won't work, at worst, it will explode. The mercury
cell is a one way reaction. It cannot be reversed.

Been there, tried that, blew it up!

Vector Electronics has a website with catalog information on it.

The wire you are mentioning is like "SolderEze" or some name
similar to that, usually found in #26 AWG size. I've used it but
would just as soon go with ordinary Kynar insultaion wire-wrap
stuff. SolderEze tended to get abrasion of the insulation, resulting
in cross-circuiting. Especially so with heat.

I got spoiled with #24 and #26 Teflon insulated solid wire, strips
easily and never abrades the insultation.

Signal to noise ratio changes as the _square_root_ of bandwidth change. Wouldn't be much of an effect going from 1.25 to 1.5 MHz.

With 0.8 uSec pulses and a 1.25 to 1.5 MHz bandwidth (I presume Mega Hertz, not milli Hertz), the output envelope will be very rounded, almost Guassian or "cosine-quared" in shape. Rounding happens because of the limitation of passing the harmonics of the pulsed RF; all you have left is the carrier frequency.

The relatively narrow bandpass and pulse rounding MAY be okay in your application. It wasn't stated. I spent some years on a program that deliberately used 1 MHz bandwidth filters for 1 uSec wide pulses on carriers 1 MHz apart. Interesting to see the effect of "matched filters" on adjacent frequencies...those immediately on each side came through with a reduced amplitude "bow tie" envelope shape, the "knot" in the middle.

It's fixed, a new day respite helps. Previously I noticed that the component board had been removed at some time becasue I could see signs of resoldered wires on the non-component side. (At that time I found a cold solder joint on R231.) I thought perhaps a wire had come off or someone transposed some. Being lazy I got the high intensity light out and thought I could see if there was a problem without taking the board out, there's only 4 screws! But before doing that I thought I'd recheck the 10K ohm Gm bridge resistors, pot and as I was connecting my Fluke to the10K resistor lead I could see it was wrapped around the post but not soldered, same for all of them. Eureka and happiness, good light helps. I took a pix and posted it at alt.binaries.pictures.radio. I soldered 4 ends and now it works like a champ and checks a known good 12AX7 as good. No more meter slamming backwards on Card 9 or power kick off and the Lo Gm pot works per spec. After more careful inspection I could see where others have tried to repair this one because I could see other signs of soldering and component replacements, some not so good. Since it was like this from the factory, it had to have been continually intermittent and became a waster of gravity. Anyway I'll be it didn't get much use and I think the condition of the switch matrix with all the waxy stuff was becasue it was sprayed trying to solve the no solder problem. This one is Serial No. 703 so if you have one near that you might want to check R 402, 403, 404, and 406 for no solder!

I'll add something from the machine shop that is probably in
the UK as well: Marker lacquer used to make marks on metal
about to be machined. Over here it is usually a deep blue and
is very dilute lacquer, obvious from the acetone odor. Various
brands, some are available in red or green (not good colors).
Scribes nicely. Brushes well with small brushes available from
craft stores.

From the drafting department of old: K&E ink pens, the two-part
cylindrical, concentric ones. Those will hold dilute lacquers and
there is a pen holder that takes the nibs. Must soak them in
acetone after using since the capilliary clearance is tiny. With
practice those pens can draw straight lines but any dilute lacquer
likes to migrate to the straightedge...:-)

Office Depot and Office Max chains over here carry the Sanford
"Sharpie" pens (permanent marker type) whose ink is ferric
chloride resistant. I find it difficult to maintain a fine nib on those
for small foil lines and prefer a small brush. Mileage varies.

I once tried acetone-diluted liquid rosin as a resist, had mixed
results. Nice odor combination while doing it. :-)

As always, with any kind of resist, the unetched copper surface
must be clean and oxide free, smooth in order to take the resist
evenly.

Have had reasonable success using the "Sharpies." What kicks me is way back when, when I bought a PCB kit from the Shack, I tried to make one and the ink came right off. I gave up - I was still young and stupid, but it was the ink that failed. A few years later, I decided to give it another go, using sharpies after reading some others having used them. I did nothing else different. The success was in the pen. Had I tried a different pen way back when, instead of giving up, I could have been very good at it by now, rather than OK. I have made a few PC boards and though "my" artistic talent isn't that great, the boards came out ok and work as intended. When I do decide to make a project, I actually enjoy going through the whole process including making the board. It is fun to go from nothing to a working item. I've made some test equipment for my shop that has saved me a few hours time already and paid for themselves in parts, time and effort. Just out of curiosity, anyone else buy the Shacks PCB kits and have any problems with the pens? OR solution? For me, the solution has been ok. MNS

Hi,
The calibration cell simply verifies that the meter is 100
microamps and a total of 250 ohms. And it contains the limit resistors
for the leakage test. I wouldn't worry about it.

Incidentally I wouldn't use any silicone lubricants on the
card-reader pins. While the original organic grease has stiffened with
time and needed to be replaced, it was probably carefully selected to
do its job. On the Cardmatics I've repaired, I've used a grease
originally supplied to General Radio by Oak, but I have no idea where
to get more of it. It was described to me by the GR engineer who gave
me some, as "Beacon M325" grease.

For noisy TV tuners back in the 1960s when I was working in a Radio and TV shop we used Lubriplate white grease that came in a small black and grey tube that resembled travel toothpaste.We sprayed the wafer switch in the tuner, rotated several times and then applied a light coating of Lubrplate with a small stick and rotated several more times. On turret tuners we cleaned the pads and wipers with contact cleaner on a Qtip and then applied Lubriplate. This was in Norman, Okla where the humidity played havoc with tuners making them intermittent and after the treatment we never had call backs. Somewhere I have a partial tube of this stuff but haven't located it as yet, so I used DeOxit on the Hickok switch matirix but would have used Lubriplate if I found it. After about more than 20 moves there's lots of possiblities where it is. Two local auto parts stores didn't have anything but silicone grease which I haven't used except as a heat transfer aid on power transistor heart sinks. I think that Lubriplate would be a good lubricant/protector unless there's something better that I don't know about. I'm guessing that there's something better after 40 yeats and would be interested in what users have used>
Now to repair number 2!

999. What use is an 829B tube?

Newsgroup: rec.radio.amateur.homebrew

Hi all,

I just found several 829B tubes - believe it or not in my garage - I must have got them in a box of stuff at a ham fest at one time. A check on Ebay shows they're pretty much worthless for the sake of dollars, but they're so COOL! With the two plate caps that are actually just stiff pins, they look like little Martians.

I put a pair on my office credenza just to look geeky cool. Fresh out of the box as NOS they look amazing - just like they were made yesterday. It's a pity they have no value - maybe as a homebrew project??

So can someone tell me what they would have been used for? Something tells me they're a VHF power tube.

Any application as a one-tube QRP rig of any sort? Any stories about using them in the past? I've built a lot of little rigs over the years, but never knew about the 829

Thanks,

Dave

Um, he was starting with an 8MHz BW...
>
> With 0.8 uSec pulses and a 1.25 to 1.5 MHz bandwidth (I presume
> Mega Hertz, not milli Hertz), the output envelope will be very
> rounded, almost Guassian or "cosine-quared" in shape. Rounding
> happens because of the limitation of passing the harmonics of the
> pulsed RF; all you have left is the carrier frequency.

Yes, the pulses will certainly be rounded when they come out of the
filter (though they may have started that way anyway). But depending
on the filter type, they may also incur lots of ringing, and if the
pulses follow one after another at the right spacing, the phase of the
energy in the pulse relative to the phase of the energy left in the
filter will matter a whole lot in what you see coming out. The
trailing edge of a rectangular pulse fed through a Chebychev filter
isn't very Gaussian looking!

As for the original question, the answer depends on the spectral
distribution of the noise...if it happens to be strongly peaked at the
carrier frequency of the pulses, the narrowing won't make much
difference; if it happens to be peaked at some other frequency, it may
help a lot. If it's uniformly distributed, AND you keep the filter
shape the same and narrow the bandwidth by 1.5:8, then you will have
1.5/8 as much noise _power_. You'll also have somewhat less signal
power, depending on the shape of the pulses. And of course, the
filter won't get rid of noise that's introduced after the
filter--fairly obvious but sometimes overlooked.

Cheers,
Tom

The last rig I saw using an 829 was about 35 to 50
watts in the 50 to 70 MHZ range.
Makes a good 2 Meter amp.
Nice tube. Not QRP IMO...
I have three of them around here somewhere.

I went from 8 mhz to 1.5 mhz,,,,
As for breaking things, the wide i.f. was stagger tuned to achieve bandwidth
and swamped with resistors, I could chop the resistors, and retune, and get
25khz bandwidth if I wanted to. It is a short pulse radar i.f., and it will
be used in a long pulse application,,,

Therefore going from 8mhz at 6db edges to 1.5mhz at 6db edges is a must. Any
narrower, and I lose object resolution, any wider, and I amplify unwanted
and detrimental noise.

They are WWII military tubes. As you surmised, mostly for VHF
work. The smaller cousin was the 832B tube, used in the
SCR-522 transmitter (driver, PA stages). A very popular conversion
for 2-meter AM through the 50s and early 60s. The modern
version of the 829 is the 5894 power tube.

1006. BFO freq how far down SSB filter skirt?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-06 03:13:05 UTC
From: Tom Holden <holden_family@sympatico.ca>
Message-ID: <6CDUb.7045$ZN1.582640@news20.bellglobal.com>
Source record: 28895

ARRL Handbook says that the BFO frequency should be at the -20dB point down the skirt of the SSB filter. Pete, KE9OA, says -24dB.
1. What is the reasoning behind these choices?
2. How critical is it that the BFO be so positioned?
3. Wouldn't the shape factor have some bearing on where it should be?
4. Is linear interpolation between the -6 and -60dB points accurate enough to determine the BFO freq?

TIA,
Tom

If you go to the DigiKey catalog (www.digikey.com) there are basically 4 manufacturers. Bournes makes some pricey ones, but they also make some small, low resolution encoders with no detents ($2.77). Pretty nice for some things. They also have a 24 pulse model for $4.86 which has very serious detents. Grayhill makes a number of encoders with fairly positive detents (series 25L, $4.70). Panasonic makes encoders with a kind of soft detent. They have a bazillion models now, ranging from 66 cents to $3.53. CTS also makes some, and I know I've used them, but I just can't remember much about them $2.58-$5.42.

None of these have the great feel of the $50 flavor, but you don't need that for a lot of things.

They are about the same as a pair of 6146 tubes in one envelope but are more
efficient at higher frequencies.
Good for about 100 watts out at 2 meters and somewhat ueuable at 440 mhz.
I think the old VHV book had an amp in it for 144 mhz that was rated for
about 40 watts out on AM and more on CW/SSB.

> patterns, but they're not as good as the Dalo for filling large areas.

Those Dalo pens are nothing but lacquer pens... Sharpies, laundry markers....even other brands of common permanent markers will work.....you can get by cheaper and have a better supply of tip sizes from ultrafine for smt work to xtra large that will cover ground planes nicely. Other permanent markers will also work. Stadtler pens are nice too, dont know their chemical makeup but they are tougher to remove than sharpie lacquer pens with solvents.

I do surface mount by hand with a double ended sharpie, one end has the normal fine tip and the other end has the ultrafine tip.
I used a piece of clear plastic to layout the patterns for common soic and surface mount resistor capacitor pads and drilled these out with a very fine drill bit used for drilling out small gas appliance orifices, it works great

Anyhow.....I have used perfboard for projects before, its quick and if you take your time you can do some really nice work. I have also used g-10 with the copper completely etched off for projects that used larger components where it was easier just to used 18 gauge wire underneath as opposed to ridiculously large traces.
For hobbyist purposes perfboard is fine.....its making sure the circuit works and works reliably that counts.

illegal under what authority ??? osha ??? They are shrouded banana
plugs,,,thats all.......I own several fluke meters along with other
brands and have many specialized test leads.....some shrouded , some
not and they work fine...even in an abusive industrial environment.
Yes, the shroud does help support the connection, this is good if the

meter gets laid down on its face or if it gets banged around in a tool bag or tool box.....but I know of know "laws" or osha regs that prevent the use of unshrouded banana plugs.

There was an article in Ham Radio, in the late eighties or so,
when someone wrote about using common pens for etch resist. He
mentioned adding some rubbing alcohol to the ink (ie pull open
the pen, and put in a bit of it) to make the ink flow better.
I know I tried it at the time, and the ink did apply better. I
can't remember if I ever etched boards with such a souped up pen.

On transmit, you need to get some of the carrier
suppression by means of the filter. Most balanced
modulators are not able to get good enough
carrier suppression when operated at low enough
levels to have good IMD. This is main reason
why phasing rigs went out of fashion.

look at (and copy) the final circuit from a BE-5A (broadcast electronics) FM transmitter.It's very simple and very stable too. It likes about 200 watts of drive from a IPA. Will run nicely with 5000 volts at about 1 amp on the plate. In the BE transmitter the tube sits in a cavity, with the plate being slide tuned. A coupling loop sits close to the tube....Eddie

1017. Will this circuit work for controlling a power relay.

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-06 06:50:55 UTC
From: James W <change-to-jw22-at-trlp-dot-com@trlp.com>
Message-ID: <1026eag5rjbgj7d@corp.supernews.com>
Source record: 28804

I need to use a 12v relay to control power to a project that is a 12V/20A load.

My plan, is to use an automotive 12v 30A relay. The relay's coils have ~80ohms of resistance. The relay has a builtin diode to handle the inductive kickback when de-energizing the coil.

I plan is to feed the emitter of a 3906 from 12v, connecting the collector to the coil, and grounding the other end of the coil.

The base of the 3906 will connect to the collector on a 4N26 optoisolator through a ~5K resistor. The emitter of the 4N26 will be grounded.

I'll be using an AVR microprocessor to drive the LED in the 4N26.

Does this all seem reasonable? I'm new at designing things like this, and though it is a simple circuit, I want it to be reliable and safe, so I'll take any criticism and or suggestions you have (about the circuit ;-)

I do not quite understand this.

Usually the signal to noise ratio is defined as the signal power S
compared to the noise N (or compared to S+N). In a white noise
environment with constant noise density, the noise power is directly
proportional to bandwidth.

If the noise bandwidth is larger than the required signal bandwidth,
reducing the noise bandwidth will not affect the signal but only
reduce the noise power directly proportional to the bandwidth
(dropping the bandwidth to 1/4 will drop the noise power by 1/4 or 6
dB and increase the SNR by 6 dB).

However, if you looking at the noise _voltage_, it will drop by the
square_root of the bandwidth. But dropping the bandwidth to 1/4 will
drop the noise voltage to 1/2, which is again 6 dB.

In the OP's case, some of the signal sidebands are also cut, thus also
reducing the signal power. Are you assuming something about the
spectral or phase distribution of these sidebands (e.g. adding
coherent side bands produce the sum of the sideband _voltages_, while
adding noise from two side bands with random phase only produces a sum
of sideband _power_).

You've gotten some good responses from some others in the NG.
The most unusual application for the 829B that I saw was their
being used to drive the magnetic-core memory modules in the
Whirlwind I computer racks on display in the Computer Museum
in Boston. The sockets may have originally been designed for
832's and "upgraded" to 829's for more drive or longer life.

20 db down is where they are usually set. It is not too critical
though. It does provide that much carrier suppression in addition.

The best way is to set it where it sounds the best. Too far down and
you get better opposite side band suppression but it also cuts the low
frequency response of the wanted side band.

Yes it will depend on the shape factor of the filter as to where the
best point on the slope is.

You can easily measure 20 db down or how far you want it by just
measuring the output voltage level from what you get at the center of
the filter. Measuring is much easier than interpolating the correct
point as only a few tenths of a cycle change on the slope will make a
large change in db down.

I used one on two meters in the early 60's. The amp was of course push-pull and had a tuned line plate circuit with link coupling. I ran AM and CW and used the modulated high voltage out of my Heathkit DX-100 for plate and screen voltage.

The original exciter was a converted SCR-522, which used the 829's baby brother, the 832 as frequency multipliers and final. Later I replaced the 829 with a 5894 and the 832s with a baby version of the '94, whose part number escapes me at the moment (6907 I think).

These later tubes were more efficient at vhf and were tetrodes rather than the 832-829 "beam-power" tubes. The 832 was sort of like a pair of 2E26s sharing a cathode and the 829 was sort of like a pair of 807s.

Eventually, I replaced the clunky '522 with a more compact exciter out of the Handbook that used somethin' or the other as oscillator/doubler/tripler and a 6360 tripler driving another 6360.

Real progress came when I converted the second 6360 to a high level mixer driven with a Central Electronics 10A SSB exciter. (I don't even want to think what the IMD out of this mess must have been.)

Many thanks to all who replied, both here and by email. They sound like a great tube for LOTS of purposes. My favorite suggestion was building a regen, using each half in place of the 6AQ5's called for in the ARRL handbook design from the 50's!

How about an oscillator / amplifier for HF, running low plate voltage for a relatively low RF output? Seems they should be able to do that - and having a separate oscillator stage it wouldn't be prone to runaway and exessive crystal current. And it would look VERY cool!

What sort of plate caps were used? There are just pins, and it looks almost as if there would have been a ceramic gizmo like a tube socket to have bridged the two of them....

Again, thanks for the info!!

Dave

To see the tube photo -- go to googe.com type in "829B tubes"
Select IMAGES not web.

I recall these in Military Aircraft of the 50's --- I believe ARC-27 -- a
UHF Transceiver by Collins Radio

The ARC-1 Transceiver used a smaller rounded version 832B -- we called them
door knob tubes -- see google

So would make a VHF/UHF power output stage maybe 10 watts or so

|3. Wouldn't the shape factor have some bearing on where it should be?
|4. Is linear interpolation between the -6 and -60dB points accurate enough
|to determine the BFO freq?
|

Perhaps an example is the best way to explain this. Assume that you
have a nominal 9 MHz crystal filter, with a 2.0 KHz BW at the -6 dB
points.

The -6 dB frequencies are thus 8.999 and 9.001 MHz. Forgetting the
bandwidth restrictions on the incoming signal, let's say you would
like the recovered audio signal to be 6 dB down at 500 and 2500 Hz
respectively.

For an upper sideband signal, the BFO should be 500 Hz below the lower
cutoff frequency, i.e. 8.9985 MHz. For lower sideband, the BFO should
be 500 Hz above the upper cutoff frequency, 9.0015 MHz.

Where these two frequencies land on the skirts is dependent on the
shape factor. These "rules" that say the BFO should be so many dB
down are really "rules of thumb" that work with typical shape factors.

They were the final in the TX of the AN/ARC-3, too. I never got
mine lit up, as I went into the USAF not long after I got mine --
surplused (or something) from the Civil Air Patrol, way back in
1964.

On the transmitter for the AN/ARC-3, the plate leads just had push-on clips with a little bit of spring-loading, much like the contacts in a tube socket.

Source record: 28819

A more normal setup would be an NPN transistor with the emitter grounded and your 5K resistor switched from the optoisolator. NPN's are generally just a bit better than a similar PNP, and you'll have a wider range of choices. A 2N3904 would work, but a 2N4401 would be a better choice.

The minimum current gain for these things is around 40, and you should design for lower yet, so you should put about 5-10mA into the base of the transistor to get it turned on good and hard. With a 12V supply rail this implies no more than a 2.2k-ohm resistor. If your optoisolator can't supply that then use an NPN Darlington instead of a single NPN.

If you do use a PNP lose the base resistor. The minimum guaranteed current gain of a 2N3906 is 60, so with 150mA collector current you'd need 2.5mA into the base - that's a 12.5V drop across your resistor, which means the circuit just wouldn't work. Even without the resistor you'll still drop some voltage in the opto, then some more in the emitter-base junction of the drive transistor. By the time you're done you'll be lucky to have 10V to the relay.

Have fun.

A nice article starting on page 40 of the August, 1949, issue of QST
describs a two-tube (6AG7 oscillator [26MHz xtal]/doubler and 829
amplifier) for 75 watts output in the 6-meter band.

Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.shortwave

I have an 80s model delco am/fm radio. I'd like to attach an external long wire AM antenna, an external FM antenna, and rig something up so I can listen to it with headphones at bedside.

Questions:

1. What do I need to do/build the headphone connection? Can I put something together using the car radio speaker wires?

2. Is it possible to hook up the long wire antenna without getting too complicated? Can I use the antenna plug on the radio in some way, or will I have to get inside the box? I don't know a lot about electronics. I have a soldering iron and have fixed the occasional loose wire on things around the house, but not much more than that.

Or should I just forget it and buy a portable receiver? I mainly want to listen to AM talk at night and a particular FM college station in the next town. I read on several posts about using a car radio because of the AM reception.

I've also thought about buying a used Grundig receiver, in particular the S350. I think having the option of listening to shortwave might be fun. Does this thing put out good audio via headphones?

Thanks.

I was looking at doing something like that years ago, using a homebrew
output transformer, but I never finished it. I do know that the 829
was used in some of the modulation decks for aircraft band transmitters
at one point, so they should be fun at AF.

> |3. Wouldn't the shape factor have some bearing on where it should be?

I think you understand. The filter is placed in relation to the AUDIO or sideband that it has to pass. The filter shape factor then determines where on the skirt the BFO happend to fall. On the type of filter (commonly) used, it appears to be the -20dB point.

Someof the other reaponses are saying the same thing in various ways.

> |4. Is linear interpolation between the -6 and -60dB points accurate
enough
> |to determine the BFO freq?

That's probablu not to bad, but the answer above says that this is going at it the wrong way. Place the filter pass band where it needs to be and the BFO goes on the carrier freq, wherever it is. If you want the filter to cut off some of the highs, then put the BFO further down the skirt - visa-versa.

If I actually answer your question and consider a "typical" (in my mind anyway) filter shape, linear interpolation will put the BFO a little too close (less than -20dB down -- as in like -18dB down) to the bandpass.

If I recall, the 829 is one of the tubes with the cathodes tied
together to a single pin, isn't it? This reduces the utility for
such things.

They are little ceramic clips. You can use Molex pins in a pinch.

You can use the speaker wires, however, the audio used to feed the speakers will be amplified, and will probably overdrive your headphones. You'll need to find a way to match the headphones to the speaker output.

> 2. Is it possible to hook up the long wire antenna without getting too

It should be easy to connect a random wire antenna to the jack of the car radio. Just solder the plug onto the wire antenna. I think they use Motorola type plugs as a standard. However, an antenna that is good for the AM broadcast band won't necessarily be good for the FM broadcast band. However, as you stated below, you just want to listen to an FM station in the next town, so a random wire antenna will probably work OK.

> Or should I just forget it and buy a portable receiver? I mainly want
> to listen to AM talk at night and a particular FM college station in

> because of the AM reception.

Well it all depends on if you're looking to do it easy, or if you want the challenge of making it work. If you're looking for a technical challenge then the car radio will fit the bill. You'll need to match the headphones to the speaker output, attach an antenna, and find a way to power it from 12VDC, either from a battery or power supply. It would be fairly easy to go buy a decent AM/FM radio for DXing (GE Superradio comes to mind).

Okay, let me restate, since I seem to be mis-understood,

The I.F. is stagger tuned, with swamping resistors to kill the Q. It is running at 60mhz with a 6db bandwidth of 8mhz. It is part of a 'short pulse' marine radar unit. The pulses were like maybe .06microseconds at about 1khz rep rate.

The transmitter now squirts out 'long pulses' of about .8microseconds. I want to raise the value of the swamp resistors, and 'un-stagger' the tuning to get a 1.5mhz bandwidth at the 6db point.

So the original question was "If I reduce the bandwidth from 8mhz to 1.5mhz, and everything else remains the same, what will happen to the signal to noise ratio in terms of db snr?

I have done similar mods before, and the units work better than ever. Just getting the swamp resistors up in value helps receiver gain more than the numbers would apparently indicate, as I can see small craft at 24 miles, when I could hardly see them at 12 miles before mods.

What specific sorts of noise are you trying to reduce? It matters,
quite a great deal.

The circuitry needed for an impulse-noise reduction circuit ("noise
blanker") is going to be a lot different than the circuit needed to
notch out narrowband interference (heterodynes or spurious-signal
"birdies"), and both of these will be a lot different than what you'd
need for a multisegment broadband audio noise reducer.

Lou
Under the black cover over the matrix swtich there are 3 black bakelite slabs (3.5" X 4.5" X ~1/4") with 187 holes sandwiching 185 pins. With the black cover removed (2 screws) and the card plunger pushed in and you'll see that the sandwich "floats" on four 8-32 threaded posts. Each of these posts has 2 nuts sandwiching the slab sandwich. The position of the lower 4 nuts (I called these jam nuts) determines how far in the 185 pins go into their female counterpart where there is no hole in the card. If there's a hole in the card the pins must not make contact with their female counterpart, and this clearance is about the thickness of a dime. In addtion all these jam nuts must be on the same plane so that the sandwich is orthagonal and will not bind so it can move smoothly.
A pix would have been easier but the batteries are being charged. Let me know if you still need a pix.

This is easily done with a resistor divider... I'd put a load
for the speaker, too. This would look like an 8-ohm 20W
resistor (RatShak sells 'em) across the speaker leads, with
a 500ohm pot across that... your h-phones are tapped
from ground to the center wiper of the pot. Adjust for taste.

Because that is just it..... It is a cheap radar with only AN 8 MHZ FACTORY
SUPPLIED I.F. BANDWIDTH which is typical of these units. The newer ones
have at least 2 bandwidths, and perhaps 3 on the really expensive units.
I would not re-invent the wheel, I just want an answer in db snr.

My answer is this, The screen full of echos looks real good after I do my
voodoo. Now, can someone just answer the question?

In article <t44820hhad9aabrveq0865vjeqfh1slcg4@4ax.com>, gaschafer@comcast.net
says...

Hallo Eddy. Thank's for responding.
I allready did some seaching for this BE-5A transmitter and i found it
manny time's. The onely problem is that photo's,schematic's or
manuals are not there.
Atleast i cannot find them. I had some more reactions on my call in
the broadcast group. The collins 830F and the harris FM-25K are alsow
transmitters with the 4CX in the final but here it's the same. I
cannot find anny photo's or manuals. I thought (when i bought this
tube)it would be easy to get some info about it becourse it it a
,,famous,,tube.

Well i wil keep on seaching........buy the way,if You know where i can find what i need,please let me know.

Regards. Onno.

That's right on! The rig was the Collins ARC-1. It used one in the final and one in the modulator. The thing was for 100-156 MHz. Later conversions for the airlines in the late 40's added 50 or so channels (sort of like the ARC-3 and the ARC-49).

Hallo Eddy. Thanks for responding. I did some seaching and i
can find this BE-5A manny time's but i cannot find photo's, schematics
,manuals wich can explane me a bit more in detail so i can build the
thing.
This time better than before,This double resonator.

If You know where i can find what i need please let me know.

Allready thank's Onno.

My guess would be that if you are using it for personal use, the OSHA
has no authority.

Also, if you are using it for personal use, then plugging a banana plug
into the jack, while negating any safety features, would not be illegal.
The jacks are actually the same as the banana jacks, but added the
extra covering over the plug for safety, so you would not damage the
jack on any way by plugging in a standard banana plug.

All this would change if you are in fact using it in a commercial
environment, because then the OSHA regulations would come into the
picture, along with others as well.

It would be easier to buy a normal radio. For AM a CCRadio or GE
Superadio 3 would work. The best FM reciever there is is the Tivoli
Audio Henry Kloss Model One, but be prepared to plunk down mucho dinero
for one ($100 last time I checked) and it's not that great on AM. I'd go
with a SR3, or you can try to get an SR2, which some think had better
build quality, but since it's (obviously) an earlier, out of production
model it's hard to find.

1056. Re: BFO freq how far down SSB filter skirt?

> 3. Wouldn't the shape factor have some bearing on where
> it should be?
> 4. Is linear interpolation between the -6 and -60dB
> points accurate enough to determine the BFO freq?

Thanks for all the useful replies! I neglected to explain that this question is related to upgrading a particular receiver and another design target is that the BFO frequency must be fixed at +/-1500Hz from the filter and IF centre frequency (1 side for USB, the other for LSB) due to the way this double conversion receiver tunes and displays frequency. So it is more a question of determining what filter bandwidth and shape would be most suitable. By targetting -20 to -24dB attenuation with this offset, I computed that example filters suited to that offset would have -6dB/-60dB bandwidths and corresponding audio passbands of:
1) 2kHz/5.4kHz ----- 500-2500Hz
2) 2.3kHz/4.7kHz --- 350-2650Hz
3) 2.5kHz/4.2kHz --- 250-2750Hz
Do these calculations seem reasonable?

Examples 2 and 3 seem to be acceptable for communications speech but the steeper the skirts the greater the risk that filter tolerances will place the BFO somewhere else on the skirts well removed from the -20dB target. Are there any economical 455kHz filters with the characteristics of examples 2 or 3 with symmetrical skirts?

TIA ,
Tom

But I did -- assuming white noise, you should gain somewhere in the neighborhood of a 6x improvement in signal power vs. noise power, which works out to around 8dB. It probably doesn't actually do that well, so call it at least 6dB. It's interesting that you see a 2x range improvement, because radar path loss goes as distance squared, so you'd expect to need 12dB improvement.

Of course when one is really proud of ones modifications one tends to look harder...

Dave, as I recall there was a design in one of the ARRL books..... maybe VHF manual that included an 829B. I also recall Motorola using this in a very old radio, don't remember exactly. Anyway I think it's good for 40-50 watts. I wouldn't mind having them if your looking to part with them.

The datasheet is here:

http://www.mif.pg.gda.pl/homepages/frank/sheets/049/8/829B.pdf

A lot of The Radio Amateur's Handbooks of the '50s and '60s had 892B projects in them. The 1953 edition, immediately to my left as I write this, has "A 100-Watt RF Amplifier for 50 and 144 Mc." on page 405. It runs push-pull class-C, up to 120 Watts CW or FM, and 100 Watts AM.

And the following fellow has gone to an awful lot of trouble to use two 829Bs in parallel single-ended triode mode in a stereo amplifier:

http://www.pmillett.addr.com/829b_amplifier.htm

The 829 was the final amplifier in the AN/TRC-1 and AN/TRC-4
VHF radio relay transmitter that was first fielded in Europe in 1943.
70 to 90 MHz, crystal controlled, phase modulation at a low
frequency, multiplied many times. Probably designed about 1941
but no data on that. Dual pentode with common cathode, plates
brought out to heavy pins on the envelope top. Pushed and
operating at maximums, it can put out about 75 W at 6 Meters.

TRC-1 and TRC-8 (high VHF) radio relay equipment was on 24/7
"hot spares" service for landline coupling backup at Army station
ADA in Tokyo up to 1954. Had literal hands-on with those. :-)
Those TRC-1 transmitters ran for hours and hours and hours without
fail, 40 to 50 Watts RF output.

A small tale on Lubriplate from Hank Kolesnik's mention in another
thread: The old radio relay equipment had separate receiver and
and transmitter cases and the TRC-1s had brushless shaded-pole
fan motors in the lids. While very cheap, those shaded-pole motors
are quite reliable. They have a (felt?) lubricant pad for sleeve
bearings; no appreciable load to require ball bearings nor high speed.

A well-intentioned newbie on one shift decided to "improve motor
performance" with Lubriplate (then a very new product in 1954) and
loaded the lubricant pads with it. While Lubriplate is a very good
product, it is a SLOW-SPEED thing. The shaded-pole fan motors
would seize up eventually, their normal light oil lubricant displaced by
the Lubriplate. For about three months it was SOP for all shifts to have

the "VHF man" check all the fans. Any fan with low or no flow meant a bothersome job of removing the fan, replacing it with a spare, then soaking the lubricant pad for several hours in solvent, saturating it afterwards in the proper light oil, checking it out, keeping it as a spare for the next stopped fan. Really put a kink in my magazine reading on the night shifts...:-) Lubriplate is a fine lubricant for dial drives and shaft bearings but should NOT be used in motor bearings.

Other than one incident with a blown fuse in one transmitter, the dozen-plus AN/TRC-1s and TRC-8s ran and ran and ran reliably.

My apologies for not stating a reference. Was thinking in terms of
voltage, a bad habit picked up with vacuum-state electronics many
moons ago. I've been working with FETs lately and am too
(for shame) conditioned to thinking in terms of signal voltages.

>In the OP's case, some of the signal sidebands are also cut, thus also
>reducing the signal power. Are you assuming something about the
>spectral or phase distribution of these sidebands (e.g. adding
>coherent side bands produce the sum of the sideband _voltages_, while
>adding noise from two side bands with random phase only produces a sum
>of sideband _power_).

Random noise POWER always adds directly. If the spectral
distribution of noise power is uniform, the noise power through a
bandwidth-limiting device is proportional to the bandwidth of that
device. Ergo, if there is a change in bandwidth, the amount of
noise power change is directly proportional to bandwidth change.

Normally for such things as radar, the receiver bandwidth is kept
wide to preserve the echo's shape (a very rectangular pulse if the

target is very reflective and a plane (not airplane) surface. The leading edge sharpness is very useful in determining precise range to the radar target.

In other applications, such as limiting the pulsed signal bandwidth to just a few sidebands on either side of the carrier, the received pulse is rounded, more rounded as the sidebands get down to just one set closest to carrier. If just a portion of the first (or major) SB set, the shape resembles the "cosine-squared" envelope, nowhere close to rectangular. That is sometimes called a "matched filter" condition where the bandwidth is equal to the pulse duration time inverse.

At RCA EASD, there was an R&D program for aircraft anti-collision that involved many carrier frequencies all spaced at 1 MHz intervals with 1 uSec pulse widths. Deliberate receiver limiting was used so the discrimination between frequencies depened highly on the matched-filter distortion. At 1 MHz away, a matched-filter would pass only the sideband content of the first two sidebands on one side; the resulting RF envelope would have a rounded "bow tie" shape with a reduced peak envelope. That made it relatively easy to discriminate against adjacent channels. While predicted in theory by the system designer, it nonetheless had a number of the senior staff (all very used to conventional RF pulse techniques) scratching their heads and doing many simulations. It worked very well in hardware but I've not seen any similar explanation in any texts before or since.

Something vaguely similar goes on in digital TV now, the video information sent digitally and the resulting digital pulse train shaped to reduce sideband content. That allows a nearly one-third bandwidth reduction so that a 6 MHz wide TV channel allotment can accept the information requiring at least 16 MHz bandwidth under conventional video modulation techniques. Obviously there is also the MPEG video compression also a part of the bandwidth reduction. Digital TV has an almost infinite S:N ratio down to the lower limit of its processing capability, none of the noise "snow" effects seen with early days of analog TV and distant TV stations "down in the mud."

Remotely, vaguely similar (:-) is the now-conventional 56K telephone line modem capable of sending high digital data rates over a 3 KHz (or less) telephone line bandwidth. While most of that bandwidth reduction is due to using a combination of AM and PM, there exists bandpass filtering of one sort or another to limit the sideband content of that combinatorial modulation. All of the techniques mentioned work in concert to present the best signal-to-noise ratio of each system.

Ever since the RCA SECANT project, I've gotten away from the conventional wide-bandwidth radar-like thinking in terms of RF pulses. Sometimes pulse shape distortion can be used to advantage. It depends on the application and not "staying in the box" all the time (holding to conventional thinking).

My apologies again for not stating my references to voltage instead of power in the previous message.

>trailing edge of a rectangular pulse fed through a Chebychev filter
>isn't very Gaussian looking!

True. "Gaussian" shape is so often used incorrectly when so many equate that to the statistical distribution curve shape also referred to as "Gaussian." Chebs and Cauers (elliptical) all exhibit ringing in an L-C component application...but it isn't quite the same kind of shape resulting with equal group delays of SAW or digital filters.

In terms of RF Envelope shape, the envelope has little hangovers at the trailing edges (I call them "burbles" in my mind, heh heh). Now, some of that comes from energy stored-and-released-at-a-later-time

(commonly called "ringing") but I think (from analysis and simulation) that it is the result of pulse sideband energy content summation that includes the relative sideband phases.

When working with SAW filters at the 3rd generation of RCA's SECANT (previously mentioned in reply to Paul), there was almost NO ringing possible (or observed) and the "matched-filter" effect was absolutely as predicted and observed in the earlier generations using L-C filters.

>As for the original question, the answer depends on the spectral

>1.5/8 as much noise _power_. You'll also have somewhat less signal
>power, depending on the shape of the pulses. And of course, the
>filter won't get rid of noise that's introduced after the
>filter--fairly obvious but sometimes overlooked.

In looking at the basic system, one has to assume that the random noise IS uniform in energy distribution. If the real world has a different set, such as peaking at certain parts of the spectrum, that can be calculated later and overall S:N modified...while keeping all the other factors the same. Any other method of looking at too many variables at once results in long hours and a marked increase in aspirin intake. :-)

I've got a copy of Claude Elwood's original "Shannon's Law" 1948 paper in the BSTJ and still need to keep the Tylenol bottle handy when I study that again. It makes sense, but getting to the "sense" part isn't intuitive. Neither is time-domain response of filters. If it weren't for the
computer simulation programs, I'd still have to rely on old aphorisms of a very general nature. :-(

I once spent a fruitless night trying to figure out the spectral content of an RF pulse that was on for only one RF cycle. The next day I brown-bagged it and hooked up some test equipment during lunch hour to get the results. Rather remarkable spectral content shape and the RF waveshape was exactly one RF cycle as observed on a wideband scope. Never did finish the analysis. Sometimes ya hafta get down and dirty on the bench to prove a point and get results.

> and everything else remains the same, what will happen to the signal to
> noise ratio in terms of db snr?

I don't pretend to be able to answer this question completely as the subject is more complicated than it would seem. However, all things being equal, SNR (Ps/Pn) is inversely proportional to bandwidth so you would expect it to increase by 10 x log(8/1.5) ~ 7dB for the values you give.

It is important though that bandwidth and pulse length match for optimum results and in "Threshold Signals", MIT Rad Labs Vol. 24, they show experimental evidence that this is indeed the case (B x Tau = 1). However you intend to reduce the bandwidth by a factor of ~5 and to increase the pulse width by ~13 (a B x Tau increase from 0.5 to 2.5) and the graphs say that this should decrease the visible threshold by ~3dB.

There are a few other things I would mention. An increase in pulse-width will increase the power dissipation in the transmitter by the same factor, should reduce target discrimination (1us is 300m and so particularly important close-in) and that a wider bandwidth is helpful in simplifying tuning or reducing constraints on the system AFC.

Cheers - Joe, G3LLV

Hi,

Sorry, I should have said "increase the visible threshold by ~3dB".

In other words, a signal would have to be ~3dB stronger to be perceived against the background noise.

Cheers - Joe, G3LLV

There's 187 holes with 185 contact pins. A17 has a threaded guide post that sets the gap (about a dime) between the two female connectors that the pins connect when there's no hole in the card. H17 doesn't have a pin nor does it have the lower female solder connection, I guess they didn't need it. Perhaps when someone has or will find a need for the 186th pin we'll have to find an extra pin and a lower female contact and a place to route and terminate the wires.

I have about 15 spare wall warts that can be used to power a wide variety of low current items.

These are Panasonic transformers, with 120 VAC in and 12 VDC at 500 mw out.

I'm using a couple to power QRP transmitters, homebrew freq counter, a keyer, and circuits in that realm.

$6.50 each includes shipping in the USA

Panasonic Model KX-A11

They come with a plug on them, the center is wired for NEGATIVE. I have cut the plugs off the ones I am using and wired them back on with the center POSITIVE. Takes about 2 minutes to do this.

Let me know if you are interested.

Hi Tom,
You can purchase the "low cost" Mechanical Filters from Rockwell
Filter Products Division, in Costa Mesa, Ca. These would be the 526-8695-XXX
series. Price, including shipping is around 86USD. The Z in/out is 2k, and
no resonating capacitors are needed, as long as your strays are below 30pF.
These are the mechanical filters that are used in the AOR3030, AOR7030, and
the Palstar R30, to name a few.
The -24dB spec is something I remember from my old HT-46 transmitter, so it
doesn't need to be taken as gospel. A good thing is to listen to how the
transmitted signal sounds.

Pete

1074. Help with dipole please?

Newsgroup: rec.radio.amateur.homebrew

Hi,
Putting up a 10 through 160 or 10 through 80 meters dipole. I have lots of wire and coax and a 1:1 balon. Interested in how the shape or form of this dipole should be to work properly? I have to put it into two trees to get height. Are there any good links or sights to learn proper making and installation?
Thanks.

I'd think running the 829 in parallel for a HF PA, with another
829 as a P-P modulator would be a neat project.

Depending on the frondend design... Early AM car radios included the
antenna feedline capacitance as part of the tuned circuit; and included
a trimmer to fine tune the radio tracking to match the antenna. The
antenna was connected to a very high impedance point of the RF
stage tank.

Later designs used aperiodic frontends, and were less critical. You
might loss ground using a long antenna on the set, depending on its
vintage.

Lots of discussion about using the 829 for VHF power amplifiers, and even audio amplifiers and conversation pieces. But I haven't seen mention here of their use in pulse generators. I have a TS592A/UPM15 pulse generator that uses one in its output stage (not all my test equipment is very new ;-), and one of the early uses of them was as a driver in "hard tube" radar pulse modulators, developed fairly early in WWII. They were used in "Model 3 hard tube pulsers" for example, where the two sections were run in parallel, outputting well over a kilowatt during the microsecond long pulse, 0.1% duty cycle. The very similar 3E29 also get lots of mention in early radar pulser history. Perhaps someone knows: was the 3E29 an 829 re-designed and/or specifically tested for use in pulsers? What was the 829 originally intended for, and when was it first introduced? Who made the first ones, RCA or someone else?

Cheers,
Tom

Hammer, An all band dipole should not be fed with coax. On many of the bands you want to work, the coax will have too much loss, and may fail due to the extreme voltages that may be present.
A better choice would be a dipole, as long and high as you can make it. Feed it with 450 ohm ladder line to an antenna tuner in your shack. The 1:1 balun should insert between the line and your tuner. You now have an all band efficient dipole.
BTW the antenna newsgroup would be better to ask this type of question, you will get loads of answers there.

Don't have answeres to all those questions but the 3E29 had a "better"
cathode to handle
the peak current requirements..

: A lot of The Radio Amateur's Handbooks of the '50s and '60s had 892B
: projects in them. The 1953 edition, immediately to my left as I write this,
: has "A 100-Watt RF Amplifier for 50 and 144 Mc." on page 405. It runs
: push-pull class-C, up to 120 Watts CW or FM, and 100 Watts AM.

Gone by the 1955 edition I have. The 1947 ed uses it in 3 2M TX circuits.

I have 3 RCA 829B and 6 or 7 slightly sturdier UK mil CV2666 equivalents,
plus some CV178A / 5894 bottles I intend to use sometime in something:-)

: And the following fellow has gone to an awful lot of trouble to use two
: 829Bs in parallel single-ended triode mode in a stereo amplifier:
:
: http://www.pmillett.addr.com/829b_amplifier.htm

These (Chinese) stereo push-pull amplifiers are commercial products:

http://www.cayin.de/amps_de/endverstarker/929D/929D.htm
http://www.cayin.de/amps_de/vollverstarker/500/500mk.htm
http://www.cayin.de/amps_de/endverstarker/800mk/800mk.htm
http://www.cayin.de/amps_de/endverstarker/800/800.htm

They substitute Russian FU29 or GU29 or US 3E29 in some.

You can get a rough translation by copying & pasting
http://translate.google.com/translate_c?hl=en&u=
in front of the links, with no space between the two.

These seem to be out of production now by the manufacturer;
they used to be on the vaccum tube amplifier link from their English index:
http://www.sparkaudio.com/eproduct.asp

RdM
(operators certificate in 1969 at 17 - never actually got on air - one day!)

A lot depends on how much space you have.

A straight dipole with a 1:1 balun and coax will only cover one band.
Well, maybe two if you cut it for 40 meters. (it'll then work OK on 15
as well)

You have a few other options:

- Make the dipole as long as possible (the exact length is unimportant);
don't use the balun; use ladder line instead of coax; and connect it to
a tuner in the shack.

- Run several dipoles in parallel. 132' for 80m, 66' for 40m, 33' for
20m, etc. They can all share the same balun and coax.

- Trade the 1:1 balun for a 4:1 and put up an off-center-fed dipole. A
132' antenna, with 44' on one side and 88' on the other, will work well
on every band between 80 and 10 with the exception of 15. (and it's
close enough on 15 that if your rig has an autotuner, it'll work there
too)

I've got the latter antenna. It's the most "bang for the buck" in my
antenna collection. (it even works halfway decent for DXing the AM
broadcast band!)

A good general rule for wire antennas is as high as possible, as
straight as possible, and as far from obstructions as possible. And
don't sweat it if "as far as possible" isn't very far. (UNLESS the
obstruction is a power line!)

Onno...call them on the phone, their support is very good. They are located
in Quincy, Illinois.

Broadcast Electronics
4100 North 24th Street
Quincy ,Il. 62305
(217)224-9600

I have toured their facility, they are a very nice group of people. The
factory is in a very quaint rural setting in Quincy. It's a "Stone-throw"
from the Harris Factory. A lot of the people that work at BE are ham radio
ops...I suspect you could get a hold of a BE-5A manual pretty easy.
Be VERY careful on the filiment voltage on the 4CX5000..it likes to be at
5.0 Volts. Don't let it sag below 4.8 Volts and over 5.25 Volts is not good
for it either. I have seen the BE-5A run at 72% eff..thats pretty
good.....Eddie

There used to be a *relatively* popular surplus rig that used three of
them. I remember they were lined up and as I recall the final had a
tuned line output link coupled to the antenna.

Don't remember what it was called. That was nigh onto 40 years ago.

I have been looking at various designs of VHF SWR bridges, mainly from ARRL sources like old QSTs and such, and I wonder if anybody here has built a device like that.
For my experience level some of the old descriptions are just a touch to cryptic or the design calls for parts which I can't locate (small feed thru caps are one of those items).
I would love to discuss this with a knowledgable builder.

Hallo Eddy.

I will surely give them a call tomorrow. Fist see what is the time
difference.
I alsow got a good advise from Umar on Amateur Broadcasting.
He was talking about a Harris transmitter.
After much digging on the Harris page i found some verry interesting
stuff.
Two schematics and some cavity drawings. All in PDF format. The
tube's they use are the 4CX3500/5000/7500 and the 10.000. The thing
i have to do now is calculate the size of the cavity and than i have
an almost comlete design.
So that is VERRY GOOD.

Eddy.....thanks for helping me out. I will let You know the
result of my phonecall what i will make with B.E.

Greetings from Elburg the Netherlands. Onno.

Don't trust the "Blown when lit" lamp for the DC Filament fuse. Don't ask me how I know because that's my fault, hi hi.....A tip that might help before attempting to clean the switch matrix that worked for me and saved some time was to insert an unpunched card into the reader and excercise it several times. The reader won't slam as positively because it forces all the pins to make contact. Next I found that 2 unpunched cards will barely fit in the reader and 2 cards will make the pins go a little further in and help clean a bit more of the shaft and their female counterparts. It slams even less positively with 2 cards but it saved me from having to diassemble the matirix. One question I can't answer is how long it will last but time will tell.
I'd like to know if anyone out there is interested in swapping me a military manual or copy of the AN/USM-118B for a copy of my KS-15874-L2 manual?
Also I'd like to know if anyone has a spare aluminum case for the Cardmatic that they might sell?

Pardon me if I'm boring you with my Cardmatic trivia but I'd like to know which of the 4 sites I posted to has most cardmatic users?

<< Pete, that's about as much as I paid for the receiver I'm trying to improve! A Radio Shack DX-394 >>

Tom-

I missed your original posting. What does the DX-394 currently use as an IF filter? If it happens to be made by Murata (or maybe Panasonic), a replacement with better specifications may available to fit in the same PCB holes. Check your filter's part number with the company's web site, and you may find a solution there.

However, if it uses the same filter for AM reception, a tighter filter could reduce sound quality of music.

Fred, thanks for your follow-up. The DX-394 has two 5-element Murata ceramic filters, one 9kHz or wider for AM and one 6 kHz or wider for SSB/CW with a BFO offset of +/-3.5kHz from 455kHz. That's why a narrower filter will need a BFO mod. There does not appear to be a much narrower filter in the same package and from what I understand Murata is out of the ceramic filter business. So I guess I will have to keep an eye out for a surplus filter or shell out $85 or so for a new 'economical' Collins!

You can probably find a surplus collins filter on ebay for about half
(or less) the cost of a new one. Fair Radio used to have 2.0 and 4.0
khz filters from the famous R390 receivers at about $25 or so.

Get a 1/8" stereo jack from RS or wherever. Use a 100 ohm resistor
between left and right speaker outputs and the jack. Too loud? Try a
higher value. Not loud enough? Try a lower value. Resistors are
cheap.

>2. Is it possible to hook up the long wire antenna without getting too

>electronics. I have a soldering iron and have fixed the occasional
>loose wire on things around the house, but not much more than that.

For normal use just put a 5 foot length of wire on it. That should
work for FM, too. It's not much different than what was on the car.

If you want to listen to distant stations a different antenna is
needed for AM and FM. I used a tuned loop antenna with a shielded
pickup loop on a mid-80's Dodge radio and it worked great. It was
selective enough to bring in stations adjacent to a nearby 50,000 watt
clear channel station (WHAM 1180, Rochester, NY).

Anyway, try it out. It will cost a buck or two and you will learn
something in the process.

Good luck,
Jim

I plan on building receivers and a simple frequency counter is needed.
Say 4 to 6 digits, up to about 50 Mhz.

I have seen approaches using:
74HCxxxx logic IC's could be made for $20 but lots of wiring

PIC - not much experience except with 16f84.
how to build programmer for lastest PIC's?

Anyone know of a demo or free digital simulation software with CMOS 4XXX
library? I have Microcap 7 demo but digital library is scarce.

So much has progressed since the MC14553 3 digit counter chips. Do they
even make them?

What frequency range , how accurate, and what do you think of as inexpensive
?
I have not looked lately but there used to be some that would work up to
about 1.5 Ghz around $ 125 or so that would get you to within a couple of
hundred Hz at 150 mhz.

1103. G5RV is the closest you can go

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-09 01:44:09 UTC
From: bobetchris <bobetchris@videotron.ca>
Message-ID: <LBBVb.27752$km5.571413@wagner.videotron.net>
Source record: 28790

It all depends on what you want to do , is it for transmit , receive, or both ?
First of all you need room, lots of it and if so what do you want, 1/2 wave, 1/4 wave or a full wave.

Assuming one wave , well on 160mtrs it would roughtly be over 400' long and you
would need heavy cables for wires and two towers or phone poles.
There is no way to set up a diapole with trees, it will snap on a windy day.

Your best bet would be the G5RV ANTENNA
THE G5RV ANTENNA, with its special feeder arrangement, is a multiband centre-fed antenna capable of very efficient operation on all hf bands from 3.5 to 28mhz, specifically designed with dimensions which allow it to be installed in gardens which accommodate a reasonably-straight run of about 102ft (31.1m) for the "flat-top". However, because the most useful radiation from a horizontal or inverted-V resonant antenna takes place from the center two-thirds of its total length, up to one-sixth of this total length at each end of the antenna may be dropped vertically, semi-vertically, or bent at some convenient angle to the main body of the antenna without significant loss of effective radiation efficiency. For installation in a very limited space, the dimensions of both the "flat-top" and the matching section can be divided be a factor of two to make the half-size G5RV, which is a very efficient antenna from 7 to 28 mhz. The full-size G5RV will also function on 1.8mhz band if the station end of the feeder (either balanced or coaxial-type) is strapped and fed by a suitable antenna tuner using a good earth connection or a counterpoise wire. Similarly, the half-size version may be used thus on 3.5 and 1.8 mhz bands.

Beware that some antenna tuners cannot match this antenna !!

This has been a hot topic recently! I just scanned an ARRL article
and a section of the test equipment chapter of the RSGB VHF/UHF
Handbook to send to someone else who is interested in making a
146/440MHz SWR monitor, and I just made a couple 100MHz-6GHz detectors
for someone else who is looking at monitoring SWR at 2.5GHz.

Seems to me the simple way for most folk to do it is to make a
microstrip coupler. You can use surface-mount components for the load
and detector and RF decoupling, and they'll work quite well up into
the GHz region, from my experience. As far as RF decoupling goes, you
should be able to do an adequate job on a circuit board...once the
detector turns the RF to DC, just put shunt capacitance to ground and
series inductance in the line. Pick the inductance as you would for
other VHF work: avoid inductors with self-resonances below the freq
of interest.

You probably have already seen the ARRL article I scanned, but if
you'd like the RSGB one, I could send it. But it's almost 4 megabytes
and may take you a while to download if you have a slow connection.

Cheers,
Tom

You might try Francesco Morgantini's (IK3OIL) PIC freq counter. It's based on a 16f84 and he will email you the hex code if you request it. It will run to approx 45 MHz as is and up to 1.5 GHz with a simple add on prescaler. He has divide functions built in the program (divide by 10/32/64) and he has also include IF offset if you want to use the counter as a freq readout. I've etched about 40 boards for local hams here and every one that has been built has worked without fail. Total cost has been in the neighborhood of $35.00 including the prescaler but excluding enclosure. If you want a copy of the circuit board layout with prescaler, just email me at ww2742 at dragonbbs.com. As for accuracy, I just adjusted one today for another local ham at it was within 200 Hz at 440 MHz using a recently calibrated IFR-1200 for a source - that was close enough for me.

Here's his website URL: http://digilander.libero.it/ik3oil/menu_eng.htm

1106. Re: homebrew VHF SWR meter

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-09 02:38:25 UTC
From: zindazenda <zen@lineisp.co.uk>
Message-ID: <1076294305.718987@smtp-1.griffin.com>
Source record: 28793

what is your top frequency you wish to use and what power levels??

you can make an swr meter good for 200w or so up to 70cms using pcb and a
very simple detector crt..
SM0VPO homepage has details..or look in rsgb vhf/uhf dx handbook..that has
microstrip (pcb) and torroid ring style bridges..they both work as i have
made many now...

Hi Tom,

No, I don't know the article you mentioned.
I just got the ARRL Antenna Book and there is a plan for a directional coupler using some plumbing hardware and I could see myself building that, but again there are some issues about available parts (thru feed caps in particular).
From my (limited) understanding these couplers would be the aquivalent of the "plugs" used in meters like the Bird 43 or the URM120.

But I am not sold on this design and would certainly want to look at the article you mentioned. And yes, I do have a slow phone connection, but if you are willing I would appreciate if you could send the article as an attachment.

Now the microstrip coupler you mention, is that what people also call a monimatch? What are the advantages of one design over another?

regards Uwe

1109. Re: Simple Frequency Counter?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-09 05:34:38 UTC
From: averyfineman@aol.com
Message-ID: <20040209003438.01632.00000652@mb-m03.aol.com>
Source record: 28796

In article <102dbbcdvmcar90@corp.supernews.com>, SWbeginner
<SWbeginner@nowhere.com> writes:

>I am looking to build a frequency counter, or buy an inxepensive kit.
>Any recommendations?
>Needs: low cost, few parts count

Recommendations depend on your intended function.

The general-purpose counter from Almost All Digital Electronics is
good, ready-built with LCD for about $40 (give or take depending on
optional backlight or BIG - actually slightly bigger - LCD, temp.
compensated timebase oscillator, etc.). Try examining
www.aade.com. A good Puget Sound area little company.

A "very low parts count" of one would be the CSI 6100 general
purpose counter from Circuit Specialists, Inc., for $129 ready to
use on either 115 or 230 VAC lines. I have one of those very
no-frills units and it works (just got it as a backup on the bench).
I've seen better displays than this one has but I can't fault the
price for a complete unit ready-to-go.

To roll your own counter-timer-etc., the Intersil ICM7216B 28-pin
DIP will count to 10 MHz by itself and drive up to 8 LEDs, has an
on-board timebase oscillator and function switching internal. The
datasheet has several schematics, fairly complete, for making
your own. Add a divide-by-10 or divide-by-100 digital prescaler
and the input frequency range can extend to 100 or 1000 MHz.
The only problem with that is that Intersil is going to OBSOLETE
the critter and is apparently out of production (unless you have a
very large quantity to order, like many thousands).

The Intersil ICM7226B is, or was, a fancier version of 7216, having
a 40-pin DIP. It seems to be all gone except on paper. Some
distributors may still have some 7216s around in stock. I have
datasheets for both and can forward them in e-mail attachments.

Several websites have nice pages on using the Microchip PIC
16F84 or 16F71 (AADE uses the '71) as a complete counter and
display driver for an LCD, extra transistor things for LEDs, using
only 3 ICs total (plus a prescaler to go higher than about 35 MHz
maximum with the PIC). That arrangement is nice because one
can program in "offsets" of the count such as reading a local
oscillator directly, then adding/subtracting the IF to get the antenna
input frequency. The only problem there with rolling your own is
that, while the PIC development software is free, and program

boards are low cost, if you aren't used to Assembler-like language and coding at the machine level, you have a large learning curve to climb. That may be worth it since microcontrollers are VERY versatile, can do amazing things with some creativity, even put ASCII legends of all kinds on the LCD screen besides the basic functions of totalizing a count. PICs of many numbers abound at distributors such as Digikey and Mouser.

To use lots of ICs of the "74" family, two to three per digit plus the timebase divider, would be the last alternative. The 74LS190 to 74F190 series is still around but the BCD versions are getting scarce; binary versions (count of 16) are there but the decade ones are apparently being dropped for new production. 74LS160 to 74F160 in the same boat. There is even a CD4nnn which has a whole BCD counter, 4-bit latch, 7-segment decoder-driver in a single DIP that will work up to about 4 MHz, higher with an input prescaler (I have to search my PDFs for the exact number).

The IC makers have been winnowing their available types over the last decade, tightening their belts, dropping some things that did not sell well (despite their usefulness to hobbyists), adding new things and getting into the SMT area with a rush that started in the late 1980s. Expect more type dropouts. Adapt, improvise... :-)

Or CRT drivers (in the AN/APS-44 aircraft radar, and I think some of
the Navy PPI repeaters).

> Perhaps someone knows: was the 3E29 an 829 re-designed and/or
> specifically tested for use in pulsers?

Probably. 3E29 was used in the Mk III IFF interogators, circa 1943. I
don't know of any other major uses for the 3E29 (AKA 829A). Real 3E29s
are getting quite scarce, but 829Bs still can be found in biblical
quantities.

> What was the 829 originally
> intended for, and when was it first introduced? Who made the first
> ones, RCA or someone else?

1943, probably RCA, although National Union was apparently an early
second source. 832 was the model for the 829.

I've seen references to the fact that the 829B was used in MIT's Whirlwind computer as core memory drivers, definitely a pulse application. I don't have any documentation on that, but I do remember some dual plate 829B-like tubes in the Whirlwind fragments that used to be on display at the now-defunct Boston Computer Museum. They could have been 3E29s, though, or even 832s.

The Univac I used 829Bs, as documented here (5/8ths of the way down the page):
http://ed-thelen.org/comp-hist/BRL61-u3.html

With that complement of tubes you could make one heck of an all-modes transceiver!

Hi Tom,
Murata did get out of the high performance filter
business.....about the only things that they have now are the
4-element CFU series, and the 6-element CFWS (now CFLW) series.

You can still find the surplus filters, but the nice thing about the 526-8695 series is that they have an input/output Z of 2K, so you can substitute these filters for the ceramic filters. Another good thing is that these new Torsional Mode filters don't require any tuning caps at the I/O pins.

It must have been some kind of coupling element.....the
regenerative circuits I have seen otherwise use a pot for the feedback
element. I did try one of those circuits, and it didn't work too well.

It's only got one large speaker, not sure if it has stereo through the
headphone jack. Heck, I'm not even sure if it does have a headphone jack.
Mine is stowed away in the camper & is mainly used for listening on camping
trips.

A standard dipole will only work well on one band. However, if you put several different dipoles together in parallel, you can have antennas for different bands using the same feedpoint.

Check out:
http://www.geocities.com/n2uhc/2banddipole.com for more information. I use a combination 20/40 meter dipole for portable operation with my QRP rigs.

Just keep in mind that the different elements for different bands will interact with each other. If this weren't the case it would be feasable to put elements for 80-10 together and use the same feedpoint. Since they do interact, you may want to put together what's known as a fan dipole, where the different elements are angled away from each other to cut down on the interaction.

I second that. I put together the DFD4 (though haven't finished it yet, need to get'r done) which is their stand alone counter. Counts up to 2 or 3 GHZ.

Unfortunately, the cost won't be that low. With the crystal oscillator option, the total cost was around $95. Website is www.aade.com, search for DFD4.

On the other hand, if you're looking for just HF & low VHF, W8DIZ has a freq counter kit that reads up to around 45 MHZ. I don't remember exactly what it cost, but was only around $40. The website is www.kitsandparts.com.

The actual URL for this kit is http://partsandkits.com/fc.asp which has a
schematic and parts list, so you could probably even build one from scratch
if you wanted. However, it's probably easier & cheaper to just buy a kit.

==========
A wire antenna between 2 trees can be very reliable provided there are no branches in the immediate vicinity of the wire and that connection to 1 tree is via a pulley with freely suspended counterweight ,such that when it is windy and parts of trees move the wire remains straight. A really simple arrangement.

CDE,

The CCRadioPlus has FM Stereo via the Headphones and LineOuts.
+ External Antenna Connections: AM is OK and FM is Poor.
+ Build-in-Speaker Sound: Designed for th Human Voice; but Good.
+ Price = $160 -&- Value = Good
http://www.radiointel.com/review-ccradioplus.htm
http://groups.yahoo.com/group/CCRadio/

The GE Superadio III 'only' has Mono-Phonic FM Sound.
+ External Antenna Connections: AM is Ok and FM is Ok.
+ Build-in-Speaker Sound: The Best.
+ Price = $60 -&- Value = Very Good
http://groups.yahoo.com/group/SuperadioIII/

The Tivoli Model One FM Stereo via the Headphones and Rec-Out.
+ External Antenna Connections: FM is Ok and AM None.
+ Build-in-Speaker Sound: Very Good.
+ Price = $100 -&- Value = Good
http://www.tivoliaudio.com/pm1blu.htm

The Grundig S350 has FM Stereo via the LineOuts
and only Mono-Phonic Sound via the Headphones.
+ External Antenna Connections: AM is Very Good and FM is Very Good.
+ Build-in-Speaker Sound: Very Good.
+ Price = $100 -&- Value = Best
http://www.radiointel.com/review-GrundigS350.htm
http://groups.yahoo.com/group/Grundig-S350/

Recently claims have been made about the better than average
AM & FM Recetion of these radios:
* Cambridge Soundworks CD 740
* Sangean WR-1 Wooden Radio
* Sangean Q Radio

FWIW: I was not impressed with the FM Reception of the Tivoli Model
One.
- In the "Urban" SF Bay Area using an Omni-Directional "X" External
FM Antenna mounted at 28Ft. The Tivoli Model One performed as well
as the CCRadioPlus, GE Superadio III, Sony ICF-2010; Grundig S350;
and Grundig Satellit 800-M.
- In the "Rural" Twain Harte,CA location Up-in-the-Hills and
Down-in-the-Valley using an FM Reflect External FM Antenna located
on the second story of the house. The Tivoli Model One did not
performed as well as the CCRadioPlus, GE Superadio III, Sony ICF-2010;

and Grundig S350.

I have an 80s model delco am/fm radio. I'd like to attach an external
long wire AM antenna, an external FM antenna, and rig something up so
I can listen to it with headphones at bedside.

Questions:

1. What do I need to do/build the headphone connection? Can I put
something together using the car radio speaker wires?

2. Is it possible to hook up the long wire antenna without getting too
complicated? Can I use the antenna plug on the radio in some way, or
will I have to get inside the box? I don't know a lot about
electronics. I have a soldering iron and have fixed the occasional
loose wire on things around the house, but not much more than that.

Or should I just forget it and buy a portable receiver? I mainly want
to listen to AM talk at night and a particular FM college station in
the next town. I read on several posts about using a car radio
because of the AM reception.

I've also thought about buying a used Grundig receiver, in particular
the S350. I think having the option of listening to shortwave might
be fun. Does this thing put out good audio via headphones?

Thanks.

> A standard dipole will only work well on one band. However, if you put
> several different dipoles together in parallel, you can have antennas for
> different bands using the same feedpoint.
==========
A single dipole will work well on many bands ,provided a balanced feeder of
300 - 450 or 600 Ohms (to name a few) is used ,obviously with a balanced to
unbalanced matching unit.
For this purpose I successfully use a 2 times 21 metres (68 ft) dipole with
a 450 Ohms ribbon feeder on all bands from 1.8 to 30 MHz. The length is not
all that critical although the dipole should preferably be half a wavelength
for the lower freq band used.
Because of its balanced behaviour the feeder does not radiate . In my case
the feeder runs into and over the loft into the lower level shack without RF
interference problems .

CDE,

ANTENNA:
You could try building a 'Low Noise' AM Antenna that can
start at near ground level and going up to as far as you
can get it and then out as far as your can make it.
NOTE: This is usually called an Inverted "L" Antenna.
* First install a Ground Rod and a short Heavy Ground
Wire at the Base / Starting Point of the Antenna.
* The Antenna Element was 100 Feet of Landscape Lighting
Cable (Heavy Duty Outdoors Zip Cord).
* Affixed the Two Wires of the Near-Feed-End of the
Antenna Element across a TV 300 Ohm Matching Transformer
and connected them one-to-one.
* Secure the The Near-Feed-End of the Antenna Element and
Matching Transformer using insulators to the Ground Rod.
* Stripped and Twisted Together the Wires of the Far-End
of the Antenna Element and covered them with electrical tape.
* Ran/Routed the Antenna Element from the Ground level
up to the Top of the First / Near Antenna Support.
* Ran/Routed the Antenna Element from the Top of the First /
Near Antenna Support to the Top of the Far Antenna Support.
* Attach 50Ft to 100Ft of 75 Ohm Coax Cable to the other
end of the Mounting Transformer.
* Attached a short Heavy Ground Wire to the 75 Ohm Side
of the Mounting Transformer.
* Ran/routed the Coax Cable from the the Antenna Element
to the your Car Radio's location.
* Terminate the 75 Ohm Coax Cable with an Motorola Connector.
* Plug the Motorola Connector into the Car Radio.
TBL: The Antenna Element is a "Flat-Thin-Loop" that is
Physically 100 Ft Long and Electrically 200 Ft Out-and-Back.

ALTERNATE: To the Random Wire Antenna is to use a CB 104"
Stainless Steel Whip Antenna mounted on a piece of 21Ft Top Rail.
* A proper Antenna Insulated "Mount" is required to be used
between the Whip and the Top Rail.
* Use a 75 Ohm Coax Cable from the the Antenna to the Radio.
* Connect the Center Wire of the Coax Cable to the Whip
Antenna Element and the Outer Shield to the Top Rail.
* Terminated the Coax Cable with a Motorola Plug.
* The Base (Butt-End)) of this piece of Top Rail should be
3Ft-5Ft in the Ground and allow the Top Rail to be Free Standing.
NOTE: The Top Rail is your Antenna and Car Radio Ground.

STEREO HEADPHONES:
NOTE: Since your did not ask about Hooking-Up a Pair of
Stereo Speakers. I assume you know how.

The simplest method of making the connection between the
Car Radio's audio power amplifier Stereo Output and your
Stereo Headphones is using a pair of Dropping Resisitors
with a 1/8" or 1/4" Stereo Jack to match-up with your
Headphones and Two Dropping Resisitors.
THE HOOK-UP: The Barrel of the Stereo Jack is Ground;
Center-Section is the Left-Side Stereo Sound; and the
Tip is Right-Side Stereo Sound. For the Center-Section
and the Tip use an Equal Value Dropping Resistor.
Here is a suggested 'value' of Dropping Resistors for
different basic Headphone Impedances:
* 4 Ohms Headphones = One 43 Ohm One Watt Resistor per Side.
* 8 Ohms Headphones = One 82 Ohm One Watt Resistor per Side.
* 16 Ohms Headphones = One 160 Ohm One Watt Resistor per Side.
* 32 Ohms Headphones = One 330 Ohm One Watt Resistor per Side.

Hi,

The 3E29 may share a similar appearance, and the same pin out as the 829, but it certainly is not interchangable. To quote the RCA TT5 manual:

3E29: Heater-cathode type containing two high-perveance units used as retangular-wave pulse modulator. Modulator Service maximum CCS plate dissipation (per tube) 15watts.

Further down, it shows the plate supply voltage as 5000V, and the instantaneous plate voltage as 5750V.

829: Heater-cathode type having midtapped heater used as af power amplifier and modulator and as rf power amplifier and oscillator.

CCS dissipation is shown as 30W with natural cooling, and 40W with forced air cooling.

It is pretty clear to me that the 3E29 was rearranged for high plate voltage, and was used as a radar modulator tube. It is designed to put out high voltage square waves.

-Chuck Harris

After 10 years I can't recall if my Hickok Cardmatic LS-15874-L2 or AN/USM-118A or B cards were ever returned or what. My remainder set is not compplete and I wonder if anyone has a set or partial set for sale. I'd also like to know if anyone has figured out an economical way to duplicate them at reasonable cost? Did Hickok make them or a contractor, anyone from Ceveland know?
On another tangent I wonder if anyone knows of any solenoids that are small enough to install on 0.25 inch spacing. With 185 of these, using extended matrix switch pins one could control the switching with a PC. I wonder if anyone recalls seeing some device that uses small solenoids that are small enough and cheap enough to homebrew a matrix. I know that this plus more has already been accomplished with relays but at $1000.00 the mod is unjustifiable for me.
Another alternative would be to have a "crossbar" of 11 by 17 rods or slats with each one driven by a solenoid, requiring the a row and column solenoid to be driven to select a pin. Having a solenoid at each end of the rod might balance the operation. This would require 28 solenoids or double that if one is needed at each end. These could be spaced on 1/2 inch centers by staggering.
If anyone has a better idea please me know but the best would be to find an orphaned set of cards.

To keep things simple and multi-band I would suggest you try to feed
your dipole with open wire feeder and use a balanced tuner. You won't
need that balun. I have been doing that with a dipole cut for 80m and
it tunes well on ALL bands (even 160, but is not that great on that
band!) and works effectively for me. Of course you will get different
radiation patterns on each band - but it works and if you have a good
tuner it can be a very efficient antenna for QRP.

I have tried using multi-leg dipoles, G5RV's and trapped dipoles for
different bands but they are harder to set-up and simply did not work
as well for me. I believe your easiest multi-band option is what I
mentioned above.

You can even make your own open-wire feeders for next to nothing and
have a much longer, less lossy feedline than you would get with RG8
coax, especially on 10metres. Get the dipole up as high as possible.
It really is very simple and effective.

Hi Uwe,

I'll try to remember to send the scan from home tonight. It is just under 4 megabytes, so it will take a while to download, but it is ten pages from the RSGB book, which seems to explain things better than the ARRL article you have (which is the one I also scanned, separately). The RSGB pages I scanned includes I think four different designs, maybe five, as well as some elemental theory.

Yes, I think the Monimatch uses coupled transmission lines, which is what a microstrip (or stripline) coupler is. The microstrip version is (generally) a piece of printed circuit board with a ground plane (uninterrupted copper foil) on one side, and a straight trace on the other side, which is the "through" line, with another trace parallel to the first trace and a small distance away, which is the "coupled" line. You terminate the coupled line at one end (to avoid reflections), and put a detector at the other end, usually just a diode detector for SWR monitoring. That tells you the power in one direction. Then for convenience, you can put an identical coupled line on the other side of the through-line, and terminate it at the opposite end compared with the first coupled line, and put a detector on it at the other end, and that monitors the power in the other direction. So you get two DC outputs, one for "forward" power and one for "reverse" power. One important point that is usually glossed-over, is that diode detectors will respond with an output voltage proportional to the input RF voltage above some level, but with an output voltage proportional to the input RF _power_ at lower levels. You should design the coupling to operate in one or the other of those regions, if you want to more easily make quantitative sense of the readings. (An even better way to do it would be to have a calibrated step attenuator between the "forward" coupled line and the forward detector, and then adjust the attenuator for equal outputs from the two diode detectors. Then the attenuator setting tells you the load's return loss, from which you can find the SWR if you wish.) It's also possible to use phase-sensitive detectors and get the complex load impedance...that's essentially what an S-parameter network analyzer does.

Cheers,
Tom

Of course, there were a couple of articles about a regen receiver that
used an optocoupler in QST. One was a straight regen, the other was
a "supergainer", ie a converter ahead of a regen detector. They had
to be in the past 4 or 5 years, though I don't have them handy. I forget
whether the optocoupler was for signal coupling, or for regen control.

You might think of microstrip or stripline as "hammered flat coax." :-)

It is just a transmission line on a PCB, the characteristic impedance
dependent on trace line width, thickness of the foil, dielectric constant
of the PCB material and, to some extent, the thickness of the PCB.

Directional couplers are simply a quarter wavelength of transmission
line (coax or microstrip or stripline) that runs parallel to the main line
connecting to the antenna. The amount of coupling is dependent on
the spacing between the two lines. Their bandwidth is typically an
octave of frequency.

Typical directional coupler coupling is 20 db down from the main line.
Power is coupled mainly in one direction, from the main line to the
end closest to the coupled line's immediate end. Some power will be
coupled into that end coming in the opposite direction but that is
usually 15 to 25 db farther down. While not perfect, directional
coupling differences of about 20 db are good enough to warrant the
name "directional." Those are very common in microwave work and
from about 400 MHz and up in frequency to around 8 GHz; a quarter
wavelength at 400 MHz gets a bit long. At 20 db coupling, the load
on the coupled line can vary quite a bit without affecting the main
line. Reflections from the load can be accurately compared with
coupled energy from the source; if coupling is measured accurately
in both directions, the VSWR can be computed from amplitude
differences. If the coupled line ends have a way to measure both
amplitude and phase, the complex impedance of the load can be
computed accurately in comparison to the coupled source.

I've built directional couplers at about 1 GHz center frequency but
admit cribbing from older published data on impedances and spacings
from microwave literature. Had a somewhat stiff specification on
coupling which required a few passes at different etch masks for a
large stripline assembly of many things. Not again if I can help it. :-)

If it is like digital cellular, it will have really good noise down to
some level _at which_ an analog signal would still be watchable (with
noise), then just DIE completely - where the analog signal would me
watchable depending upon the viewer's noise tolerance.

If you live in the UK try looking at www.cumbriadesigns.co.uk
They do a nice little kit for a counter that should easily reach
100MHz. The cost is around ï¿½50 UK I believe (say $85 US). They also do
a similar module for use as a digital readout dial replacement for
older transceivers.

If you are not in the UK I believe the web site quoted above would
still be of interest to you.

Good luck,

Peter, G3PHO

> >Now the microstrip coupler you mention, is that what people also call a
> >monimatch? What are the advantages of one design over another?

I believe this is correct. It's been a long time, but I should look at
an old handbook to make sure I'm thinking of the right thing. I'm
thinkin' of the version where you "snake" another wire under the shield of a
piece of coax for the pickup.

Side bar: I have one of the first directional power meters, the Micro
match. It uses a resistor, yes, resistor, for the current sense rather than
the now common current transformer toroid. circa 1945 -50.

> You might think of microstrip or stripline as "hammered flat coax."
:-)

The accepted terminology is "Stripline" (think "strip transmission
line") for the line with two flat ground planes on either side of the
"center conductor" which can be thought of as this flattened coax....and
"micro strip" (I have no memory aid) for the one that is one-sided where
the "center conductor" is on the top of a PCB with a ground plane on the
bottom..

> It is just a transmission line on a PCB, the characteristic impedance
> dependent on trace line width, thickness of the foil, dielectric
constant
> of the PCB material and, to some extent, the thickness of the PCB.

I think the PCB material (thickness & properties) has a larger
contribution to the Zo that the runner thickness...at least at the freqs I
worked at (<1GHz.). Good ole' Wheeler & Sobol equations for the Zo.

> Directional couplers are simply a quarter wavelength of transmission
> line (coax or microstrip or stripline) that runs parallel to the main
line
> connecting to the antenna.

I believe a 1/4 wave is not important here. The coupled line can do this
without such a long line. As in the coveted Bird wattmeter "slug", which
has a very short coupled line inside. For understanding just think that

when you put two "center conductors" into a coax, some power will be coupled over to the second one from the first & visa versa. The physical construction determines how much. I will call this added line the "secondary" one.

A bit of the power on the main line gets sent to the coupled (Secondary) line, but it emerges in the opposite direction--this is the "correct" end referred to below.

So you have four connectors. Two for the main line and two for the secondary line.

> Typical directional coupler coupling is 20 db down from the main line.

This is a matter of choice by the manufacturer construction. What this means is that the power coming out the (correct end of the) secondary line is 20dB down (1/100 th) from the power on the main line.

> While not perfect, directional
> coupling differences of about 20 db are good enough to warrant the
> name "directional."

This is a matter of primarily the mechanical design. The "directivity" refers to the amount of power that gets coupled to the secondary line that emerges out the "wrong" end--not the one we want. High or good directivity = little coming out the wrong spigot. With 20dB of directivity, the power emerging from the _wrong_ end of the secondary line is _another_ 20dB below that merging out the correct end of the secondary line. So it is 40 dB down from the main line power. And don't forget conservation of energy. All this "coupled" power is stolen from the main line.

They both should have a nice (50 ohm) impedance and be loaded with 50 ohms as well. The better it is constructed, the less energy is coupled onto the coupled-line in the wrong direction. If done well, the directivity is highest. [The secondary line can have other than 50 ohms, but common use requires it] For the Moni-Match (snaked type) the secondary lines could be some weird Zo and all is well if it is matched pretty well.

Snaking the extra wire into a coax is crude. I don't know what the Zo would be, but it works ok as long as the coupled power has reasonable directivity. Remember, the better the SWR using one of these, the worse the accuracy, for this reason. The power coming out the wrong end of the secondary line corrupts (adds to) the reflected power you are trying to measure.

By the way, you can pump power into the secondary line and have some come out the mainline as well. This is actually done for special uses.

Hi gang,
I know there are several professional engineering types on the list, so I thought I'd post this here. I teach at a technical college and it is budget time. My boss asked me for a "wish list" and a vector network analyzer came to mind. What I had in mind would be something we could use to characterize small signal BJT and JFET circuits at say 3-30MHz. VHF and UHF would be nice, but not required. I'd be looking for something that could provide real and imaginary values, so as to be able to develop s parameters for various circuits.
In order to qualify for consideration, the unit would have to be new, and non-kit. :(I know HP and others make things like this. Any recommendations?
BTW, I know something like this is going to run in the kilo or tens of kilo buck range. Hey, it's their money and they asked. ;) ;) ;)

Thanks for the input.

Bob WB0POQ

50-100w at 2m....look at harry's site...sm0vpo...harry's homebrew..

there is a design there that will do you fine..even has the pcb design for you..it works fine..i have tried it..you can make the pcb smaller if you wish.i have used it no problems with 200w at 2m...50r line is 2.8mm with 1/16inch fibreglass pcb, so you can design your own..its not critical how far the sense lines are away from the50r through line,(if you are just after swr bridge) just remember to terminate each (oposite end) with 100r resistor..i have even hand drawn the board and it works fine too....any old diode works too..i can here the keypads typing away saying you must use this diode or that diode, but really use what you have..0a91's will be more sensitive than 1n4001's but who cares at 100w???

if you are after a acturate piece of test equipment then ignore all above..but for working easy to build, cheap, swr meter then you can not go wrong.

n.b. see vhf/uhf dx handbook (rsgb) for similar more accurate (in power terms atleast) swr bridges..

Chuck Harris <cfharris@erols.com> wrote:
in rec.radio.amateur.boatanchors<4027a0eb$0$3196$61fed72c@news.rcn.com>,

: Hi,
:
: The 3E29 may share a similar appearance, and the same pin out as the
: 829, but it certainly is not interchangable. To quote the RCA TT5
: manual:

Hi, Chuck. "Certainly" is a strong word. In this case, I'd take issue with
your conclusions from those pages of the RCA TT5 manual ... see below:

: 3E29: Heater-cathode type containing two high-perveance units used
: as retangular-wave pulse modulator. Modulator Service maximum
: CCS plate dissipation (per tube) 15watts.
:
: Further down, it shows the plate supply voltage as 5000V, and the
: instantaneous plate voltage as 5750V.

Emphasis on "Modulator Service" for both of those paragraphs ...

: 829: Heater-cathode type having midtapped heater used as af power
: amplifier and modulator and as rf power amplifier and oscillator.
:
: CCS dissipation is shown as 30W with natural cooling, and 40W with
: forced air cooling.

For Class C Telegraphy (and only natural cooling & CCS shown at AF)
De-rated plate voltage and input 89% above 250MHz. Different services.

However, compare the transconductance and mu factors - identical, as are
heater requirements, and as are the three interelectrode capacitances given
- almost; G1 - K, G2, G3, heater mid-tap is 14.0 vs 14.5pf.

It is not inconceivable IMO that "Bill K7NOM"'s assertion that the 3E29 had
a "better cathode" might explain a 0.5pf difference, and that an otherwise
very similiar tube might be derated 50% in plate dissipation for pulse duty.

: It is pretty clear to me that the 3E29 was rearranged for high plate
: voltage, and was used as a radar modulator tube. It is designed to
: put out high voltage square waves.
:
: -Chuck Harris

Given the identical transconductance and mu factors, mostly/almost identical
interelctrode capacitances, and (I assume, not having seen one) similiar if

not identical external appearance in construction, I don't think it could have been "rearranged" very much. I'd hazard a guess that they *are* interchangeable, at least downward, (ie 3E29 anywhere you'd use an 829B) if not 829B for pulse duty. Perhaps they are the same within 829B ratings?

Furthermore, the 1962, 1955, & 1947 ARRL Handbooks I have all list 3E29/829B together, with ratings on the same lines, and G1/fil capacitance as 14.5pf. The latter two also list 829 and 829A, separately, from 3E29/829B together.

It's actually comparing transconductance, mu, and interelctrode C's (let alone typical AF Ra-a figures) that led me earlier to entirely reject loose statements like "they are essentially two 807's (or other) in one bottle".

IIRC, there have been mentions elsewhere that RCA may have labelled identical tubes differently for different services. I think Ned Carlson of Triode Electronics said something about this on rec.audio.tubes once, but I can't find it on a brief look. IOW, marking as different for marketing ...

Here's another suspiciously similiar example from RCA TT5. You know that 6883 and 6159 are identical with 6146 except for heater ratings. Now have a look at 6293 and compare the above factors (& outline, base, etc) with 6146.

Identical, *except* that it's listed for pulse duty, and "Rectangular-Wave Modulator maximum plate dissipation, 10 watts." (ie half, as per 3E29/829B)

What's the bet that you could use a 6293 anywhere to replace a 6146? :-) Vice versa? Is it possible that RCA labelled tubes for different markets?

Maybe the pulse tube versions (if they were such) of otherwise standard transmitting tubes had somewhat better emission or other cathode tinkering for the very high (though short duty) pulse currents; perhaps they were pumped out longer for a harder vacuum; - I speculate, but there do seem to be a few cases where they appear identical (except for pulse plate diss.) with different numbers. IIRC too, there are some tubes with both pulse and normal ratings I've seen data for, but I can't remember any offhand - it would be interesting to compare the plate dissipation for both duty classes.

Cheers!

Ross Matheson

Hi Ross,

It certainly could be that they are very similar inside.
I have used the 829B, but I have never had my hands on a 3E29.

Purely speculation on my part, but I would guess that the 3E29 has
fewer sharp edges inside to help prevent arc over and other funny
stuff at the 6x increase in plate voltage. I would guess that the
cathode is made of much sterner stuff, and the vacuum is purer.

They make a special point of saying that the 3E29's mu will always
be within 10% of the spec'd value. That tends to indicate that more
care was taken with internal tolerances, particularily cathode to
control grid spacing.

The part I find odd is usually when RCA is listing a similar tube
they will say something like plate curves match 6L6, or some such.
There is a total absence of mention of the 829B in the 3E29 spec
sheet.

What do you want to bet that the 3E29 also cost 3x the 829B?

Anybody have a 1950 price sheet?

I have a number of very nice HP counters for frequencies from 20Hz to
1.3 GHz. Prices vary depending on what frequencies and features you
want over a range from $60 to $200. They are all very high quality and
extremely accurate. These are small AC powered units.

Email me for a list if you think you might be interested.

Evening all,

This is a good question. I too have a LS-15874-L2 that came with the small deck that supports only Western Electric tubes and have thought about seeing if I could get new blanks made so I could program my own tubes as needed. Has anyone done this in the past? If so were the cards usable?

On the other hand, if you are using modern low-impedence headphones,
just attaching them across the speaker wires may work well enough.

Of course, you'd probably want to add a phone jack with an extra contact
to cut the speaker out of the circuit when the phone plug is inserted.
With a little thought, you might even be able to add a resistor or two
to adsorb some of the "extra" audio that went to the speaker.

Yes! But, I didn't want to rub that in to homebrewers. :-)

Sigh, I'm way overdue for searching electronic dumps for teflon covered wire...old nylon-jacketed PVC is still old and still melts.

[I'm secretly glad no one remarked on the extra T in 'insulation,' that would be instigation of insulting the insulation installation... :-)]

That's quite probably true. Textbooks have the "correct" description
but some in the RF field get over-wrought about terminology and
techno-propriety. :-)

Either type of physical construction makes a TEM (Transverse
ElectroMagnetic) transmission line, just like coaxial cable.

> I believe a 1/4 wave is not important here.

For an octave bandwidth and even coupling it is. Those directional
couplers show about less than +/- 1 db difference in coupling versus
frequency over that octave. If the object to obtain a low phase error
over frequency as well as magnitude, then there has to be adherence
to "traditional" shapes-configurations.

ANY conductor running close to and parallel to a transmission line
center conductor will couple something into the coupling line.
For a dual coupler arrangement in SWR checking by magnitude
alone the actual coupling values in db aren't all that important in
getting a relative reading of forward versus reverse.

>> Typical directional coupler coupling is 20 db down from the main line.
>
> This is a matter of choice by the manufacturer construction. What this
>means is that the power coming out the (correct end of the) secondary line
>is 20dB down (1/100 th) from the power on the main line.

I'll say that it is a value chosen by the users...manufacturers make
all kinds of coupler coupling values but most seem to go to the 20 db
value because it is a compromise between coupled signal strength
and the effects on the main line from the coupled line and its varying
load impedances. With 20 db coupling (1/100th power as you noted),
the main line is hardly affected whether the coupled line is terminated
in proper resistive value or open or shorted.

>> While not perfect, directional
>> coupling differences of about 20 db are good enough to warrant the
>> name "directional."
>
> This is a matter of primarily the mechanical design.

Mechanical AND electrical...that also influences the directivity.

>The "directivity"
>refers to the amount of power that gets coupled to the secondary line that
>emerges out the "wrong" end--not the one we want.

"Directivity" values are the sum of forward coupling and reverse
coupling. If a coupler has 20 db coupling and the directivity is
45 db, the reverse coupling is down 25 db. [numerical example
only] "Single" couplers have only 3 ports. "Duals" have 4.

>from the main line power. And don't forget conservation of energy. All
>this "coupled" power is stolen from the main line.

At 20 db coupling, a bad coupled line termination results in a 1%
change of the main line power level. Small value, hard to measure
or hard to see on a meter.

> They both should have a nice (50 ohm) impedance and be loaded with 50
>ohms as well.

Only if that is the main line characteristic impedance being used. The
TV cable folks work with 75 Ohm Zo and have couplers for that main
line with no problem.

>requires it] For the Moni-Match (snaked type) the secondary lines could be
>some weird Zo and all is well if it is matched pretty well.

But...the amount of coupling CAN vary considerably with frequency
even though direction of coupling has an good relative agreement.
I'll base that on measuring the "snaked-through-the-large-coax" kind
(two different versions) intended for higher HF bands that had about
15 db difference between the two of them AND had quite a variation
in coupling over frequency. Did that about 40 years ago and didn't
get to keep the notes. Did the same with a rigid copper pipe coax
section having a slot for insertion of a coupling line about 30 years
ago and it was more even in coupling over high HF and reproducible
(based on the same measurement set-ups used by another to check
duplicates shortly thereafter).

To make duplicates of an article's presentation requires a slavish
devotion to copying EXACTLY as described. It's not a case of just
snaking it through the coax, running alongside the outer conductor
braid...which can result in a remarkable variance from the original due
to coax flexibility. With all the available copper piping in many sizes
in home repair stores, the choice of spending a bit more time rather
with a piece of flexible coax will be far more worth it in the long run.

>By the way, you can pump power into the secondary line and have some come
>out the mainline as well. This is actually done for special uses.

3 db couplers, also known as "hybrid couplers." Very good for making
wideband push-pull or push-push amplifiers out of modular amplifiers.

I'll just add that some directional couplers, both single and dual, are
made with double-sided PCB material, the coupled line on one side,
the main line on the other. Those seem to be good (as products) only
to about 4 GHz or so due to variation in dielectric constant and board
thickness variation. The tiny versions of the last decade use "hard"
substrates of ceramic, etc., and the so-called "blue line" of co-fired
construction from Mini-Circuits is an example. High dielectric constant
in substrate allows making them smaller and the material insures
stability and good control in manufacture.

Once something to be used for measurement is done, there is no
guarantee that it will work as planned. Separate testing needs to be
done to prove it out. That requires measurement with accuracy of
power levels of large dynamic range. The microcontroller display
power meter using an Analog Devices log detector is excellent for
that purpose, dynamic range as large as the basic log detector's
specs. Those seem to be popular in Denmark and Germany according
to the number of ham websites and commentary and photos therefrom.
Search under "power meter" and ignore the commercial hits to find
several ham sites having such homebuilt meters.

At a hamfest on Sunday, a trader was selling teflon insulated
silver-plated stranded hookup wire in two sizes, as "aerial wire". I
bought 50 metres, but by no means all of it is going up in the air.

Len, you said it "strips easily"... well, maybe I haven't found the
right kind of wire strippers yet. What kind do you use?

: Hi Ross,
:
: It certainly could be that they are very similar inside.
: I have used the 829B, but I have never had my hands on a 3E29.

Ditto. (Well, I haven't actually *used* them yet - they're still NIB! :-)

: Purely speculation on my part, but I would guess that the 3E29 has
: fewer sharp edges inside to help prevent arc over and other funny
: stuff at the 6x increase in plate voltage. I would guess that the
: cathode is made of much sterner stuff, and the vacuum is purer.

I have seen mention of harder vacuum and tolerances in pulse-rated tubes.

Ned, in a 1997 r.a.t post, compares a pulse-rated 4PR65A to a 4-65A, itself already having a higher vacuum than your average receiving tube, and notes that the latter wouldn't sub for the former. [http://tinyurl.com/3c5wx] Elsewhere he mentions 4-400A and 4PR400A. Eimac numbers, I think.

: They make a special point of saying that the 3E29's mu will always
: be within 10% of the spec'd value. That tends to indicate that more
: care was taken with internal tolerances, particularily cathode to
: control grid spacing.

Quite possibly. I hadn't heard the 10%. Top of the bell curve selection?

: The part I find odd is usually when RCA is listing a similar tube
: they will say something like plate curves match 6L6, or some such.
: There is a total absence of mention of the 829B in the 3E29 spec
: sheet.

Exactly my point with the 6146 equivalent examples, all from TT5.
All listed as sharing 6146 data except for that very alike pulse tube 6293.

Yet, again, the ARRL Handbook data section has 3E29/829B sharing.

That German audio retailer with the Chinese amps has them using 829B, 3E29, or GU-29, implying AF similiarity. There's a clear picture of the GU-29 at: http://ly1dq.hypermart.net/gu-29.htm (and a simple 2M TX example at http://ly1dq.hypermart.net/exam/gu-29_01.gif , to stay slightly on topic:-)

: What do you want to bet that the 3E29 also cost 3x the 829B?

(:=}) Quite possible, since military or other radar the likely application.
Plus it likely wouldn't do to say "Just use our 829B, it'll work fine" ;-)

They must have at least been "selected" or perhaps built to better specs.

It wouldn't make sense to be building an essentially identical tube too
differently. A subtly different cathode coating, perhaps, for the different
pulse current requirements? (like starting batteries vs storage) (total
speculation on my part!) and a longer time on the vacuum pump would be easy
to arrange on the same production line, with the build otherwise identical.
Perhaps harder vacuum plus statistical selection alone would be enough?

Ah! I've been scrolling through my files, and found some text on 829B/3E29
I'd saved from the Joenet archives (someone building an amp with one or two)
in which Gary Longrie says "Same tube, but the 3E29 is pulse rated, can hold
off 5kv, being built with ceramic parts."

I don't know how true this is ...

I notice that the UK mil CV2666 has a completely extra top mica disc above
the plates, extending all the way to to the glass, with ceramic inserts, as
well as the bottom metal disk with ceramic inserts like the RCA 829B.

It just occurred to me to do an image search on 3E29. Sure enough,
http://www5b.biglobe.ne.jp/~tritium/rca3e29-1.jpg
http://www5b.biglobe.ne.jp/~tritium/rca3e29-2.jpg
http://www5b.biglobe.ne.jp/~tritium/rca3e29-3.jpg

http://home.snafu.de/appelt/tubes/3E29.jpg

It looks the same as the RCA 829B that I have here, as far as I can see.

Hmm. http://hereford.ampr.org/cgi-bin/tube?tube=3E29
-
"Maximum Ratings (Design Center Values)

Plate Voltage ..... 750 Volts
Grid No. 2 Voltage ..... 240 Volts
Plate Dissipation ..... 40 Watts
Grid No. 2 Dissipation ..... 7 Watts

For other characteristics and typical operation, see 829B"

–

http://www.r-type.org/exhib/aaa0174.htm shows 829B (& "=" 3E29)

Commentary mentions the superior European double tetrodes, which

"made the 829B and 832 obsolete, and offered greater output power.
This valve type would not have been the valve of choice by 1950.
Currently, designs exist to use all of the VHF double tetrodes as audio
amplifiers, these are physically beautiful devices and deserve to be seen."

: Anybody have a 1950 price sheet?
:
: -Chuck Harris

That would be interesting, too.

RdM

[obviously with too much time on his hands right now, but likes his 829B!]

Oddly, after all my previous post, I hadn't looked at an RCA 3E29 spec.
This old one (TT?) from 1946, does say " Similiar to type 829-B, but
intended particularly for pulse modulator service."
http://www.mif.pg.gda.pl/homepages/frank/sheets/049/3/3E29.pdf

Still unclear on what makes the difference, though.

: clips with a little bit of spring-loading, much like the contacts in a
: tube socket.

In the RSGB Amateur Radio Handbook 3rd Ed. they went so far (full construction details) as to give details of a drilled and tapped (for grub screw) 3/4" x 5/16" brass rod, for QQV06-40 / 5894 (has thicker pins)!

You might consider using the brass inserts from terminal connector blocks, which already have grub screws and come in at least a couple of sizes.

Since the anode tank circuits then often used flexible copper strip to possibly more brass rod in these British circuits, a bit of heat-sinking would be taking place as well, I think. May as well use a heavy contact.

The 829B needs external neutralising, unlike 5894 with it built-in.

I could scan the few pages of the 1947 ARRL I have showing 829B, but you might want to find the few years following for more, maybe improved ones.

You can buy a HP 5328A or B on EBay for less than $50. Even the nixie 5326B which is ancient -- will provide many more years of service. These two can be described as "ubiquitous". The 5334 is also a very nice two-channel unit.

Can't argue with the above but my memory says that the high currents in
pulse duty could strip
material from the cathode. The pulse rated tubes had a more robust
cathode. That was a long

time back so can't be sure of my facts at this time

Also, make sure that one end of your dipole is fastened to the tree
with a weighted pulley system, so that when you get strong winds the
dipole won't snap. I run the line through a small pulley attached to
the tree and then hang a brick off the end of that line. Works very
well in winds to give the dipole some give.

Not really all that uncommon. A Wheatstone bridge works fine for
monitoring SWR, and transformer-coupled versions of essentially a
Wheatstone bridge are commonly used in S-parameter test sets used with
network analyzers. Nice for flat response over lots of octaves, if
you are verrrry careful about the construction.

(And though stripline is true TEM, microstrip is quasi-TEM because of
the different dielectric above and below the microstrip.)

Yep, by far. The free "RFSim99" program will help with the dimensions
for five different kinds of couplers, you pick the coupling, including
stripline and microstrip. The one thing it fails to mention is the
1/4 wave line length for the given coupling.
>
>
> > Directional couplers are simply a quarter wavelength of transmission
> > line (coax or microstrip or stripline) that runs parallel to the main
> line
> > connecting to the antenna.
>

> I believe a 1/4 wave is not important here.

Right...but beware of NULLS in the response at integer multiples of 1/2 wavelength, and the response returns to the same value at 3/4 wave as it was at 1/4 wave. They are broadly rounded peaks, as Len says useful over perhaps an octave for non-precision power measurements. This can be used to advantage for a 146-440MHz coupler: make it 1/4 wave at 146, and it will respond fine at 3/4 wave at 440. But 1/4 wave (even with the 0.5 VF of glass-epoxy circuit board mtrl) is a bit long. But...you can fold that in a "U" and get it down to ten inches or so board length.

For broader bandwidth, it's common to make the stripline or microstrip in three (or five, or...) sections with varying coupling. The center section is highest coupling, and the outer sections are lower. You can find design info on the web about this. The broadening is quite significant.

...
> > Typical directional coupler coupling is 20 db down from the main line.
>
> This is a matter of choice by the manufacturer construction. What this
> means is that the power coming out the (correct end of the) secondary line
> is 20dB down (1/100 th) from the power on the main line.

In fact, -20dB with 100 watts input gives you a WATT at the "FWD" output, which is WAY more than I want to deal with! Simple diode detectors let me "see" down to -50dBm, so even a milliwatt is really more than I need. Even with 10mW of excitation, a -30dB coupler is quite useful. DESIGN the coupler to give you what you want at the output!
>
>
> > While not perfect, directional
> > coupling differences of about 20 db are good enough to warrant the
> > name "directional."
>
> This is a matter of primarily the mechanical design.

AND the loading on the "other" end of the coupled line. Steve touched on this, but I think it deserves more emphasis. Consider: if you have a -20dB coupler and 100 watts forward and zero return on the "through" line, you have a watt trying to come out the "forward" coupled port. If you don't terminate that perfectly, some of that watt goes back the other way, and spoils the directionality. SO...if you screwed up the trace width (perhaps because you didn't know the dielectric constant or thickness of the board material exactly, or your etching wasn't perfect), you can still adjust for very nearly perfect directivity by adjusting the load on the coupled line. This is also why it's good, especially at microwaves, to NOT try to use two detectors on opposite ends of the same coupled line, because the detectors are more difficult to have be really good resistances and not introduce

parasitic reactance. One way to make the load adjustable (assuming low enough coupled power that you can use SMT resistors) would be to provide pads for multiple termination resistors (two or three) and use a parallel combination that gives you just the right termination. This assumes you have a really good load (including any line and fittings) you can put on the through-line to insure near-zero reflections there! Calibration-quality loads for GHz frequencies are NOT cheap, and garden-variety coax is practically guaranteed to NOT be 50 ohms exactly. (45-55 is about the best reasonable expectation you should have for RG-58.)

...

Cheers,
Tom

I find that that system works well, though I've had to use a cinder-
block instead of a brick. I suspect that the weight of the mass on
the line is dependent on circumstances too numerous to enumerate.

Here in Oklahoma, it also serves well as a combined wind speed gauge
and wind direction indicator.

> ElectroMagnetic) transmission line, just like coaxial cable....

Not getting religious about it, just adding some info here & trying to
clarify/simplify the explanatin. The OP asked if the "Directional coupler"
being talked about was like the Moni-Match. I was just trying to make that
case---then, as is common here, to add a lot of stuff I felt was helpful in
explaining what I thought the OP _may_ want to know...if he/she didn't give
up on the long post hi hi

> > I believe a 1/4 wave is not important here.
> For an octave bandwidth and even coupling it is.
> ...If the object to obtain a low phase error...

I didn't think the OP was asking about octave bandwidth or phase.
Perhaps I missed that.

> ANY conductor running close to and parallel to a transmission line
> center conductor will couple something into the coupling line.

That's the idea I was trying to point out. Like What I call the "snaked
wire" version.

Then we get into deeper detail and possibly symmantics. I'll keep my
symmantics comments to a minimum since I was simply trying to provide a
simplified comparison with the monimatch and a little info on how they work.

> >> Typical directional coupler coupling is 20 db down from the main
line.
> > This is a matter of choice by the manufacturer construction.

> I'll say that it is a value chosen by the users...manufacturers make
> all kinds of coupler coupling values

And I meant that when a given coupling is desired, it is the physical
construction which gets you there.

> ...With 20 db coupling ...,
> the main line is hardly affected whether the coupled line is terminated
> in proper resistive value or open or shorted.

Sure. Weather or not you pull 1% of the power out, few of us will care.

> >> name "directional."
> > This is a matter of primarily the mechanical design.
> Mechanical AND electrical...that also influences the directivity.

Again, I was merely pointing out that good construction is necessary for
good directivity. In contrast to the "snaked" coax version which can have
highly variable performance.

> >The "directivity"
> >refers to the amount of power that gets coupled to the secondary line
that
> >emerges out the "wrong" end--not the one we want.
>
> "Directivity" values are the sum of forward coupling and reverse
> coupling. If a coupler has 20 db coupling and the directivity is
> 45 db, the reverse coupling is down 25 db. ...

I presume you intend to mean"...from the foward _coupled_ level." ???
This is what I was trying to say.

> And don't forget conservation of energy. ...
> At 20 db coupling, a bad coupled line termination results in a 1%

Probably going too far for the OP's original need I guess I'm just as
guilty of adding mounds of information that he OP might not be interestred
in.

> > They both should have a nice (50 ohm) impedance ...
> Only if that is the main line characteristic impedance being used.
That's why I put the 50 in (), just as an example. I should have left
it out, but then I figured a question of "what is 'nice'" might have
surfaced.

> >...For the Moni-Match (snaked type) the secondary lines could be
> >some weird Zo and all is well if it is matched pretty well.
> But...the amount of coupling CAN vary considerably with frequency
> even though direction of coupling has an good relative agreement.

Sure. Again, I don't thing the OP is worried about flat freq response.
Many of us are familiar with the switched SWR meter with the pot to set the
FWD power to full scale and how that varies from band to band. We live with
it. At work, however, flat couplers are needed.

In fact, I was doing it last night. Was puzeled by the worse SWR on
teh lower bands of a high quality load. Could be... the SWR meter..
.

> I'll base that on measuring the "snaked-through-the-large-coax" kind
> (two different versions) intended for higher HF bands that had about
> 15 db difference between the two of them AND had quite a variation
> in coupling over frequency.

Do you remember if you looked at the Zo of the coupled lines? I seem to
recall that in the articles, the termination of the coupled line is
considered an emperical optimization. cut-try for the value of load giving
"best" operation. I also wondered about the load seen at the end(s) where
the detectors were. Did they get a good match there. That;s going to mess
with your directivity, no? I guess you can put a good load on the main line
and just tweek for best directivity... a.k.a. lowest reading when line
matched - in BOTH directions. Seems that this is all you need to worry
about, for a ham, that is.

> To make duplicates of an article's presentation requires a slavish
> devotion to copying EXACTLY as described.

Again, that's where my comment about mechanigal construction came from.

> >By the way, you can pump power into the secondary line and have some come
> >out the mainline as well. This is actually done for special uses.
> 3 db couplers, also known as "hybrid couplers." Very good for making
> wideband push-pull or push-push amplifiers out of modular amplifiers.

Won't go into detail, but high power linear amplifiers (60dB 2 tone IM)
in the 800MHz & 1800MHz range use 20 dB couplers for "Feed-Forward" IM
correction loops. Made an extensive "Backplane" with many stripline
couplers for them.

> ...High dielectric constant
> in substrate allows making them smaller and the material insures
> stability and good control in manufacture.
I have used Alumina. I also saw an article on microstrip couplers with
a complementary zig-zag pattern on the edges of the coupled lines adjacent
to each other...forget what the advantage was...I think increased coupling.

> ...Analog Devices log detector is
I saw that little bugger in QEX. Pretty cool!

It might be possible to find a donation, too, and of course that wouldn't have to be new (but might be). My specific recommendations would be biased so I'm going to avoid giving them. However, I think you should make a wish-list of features, first, and perhaps your students could help you come up with those. It would even be a chance to engage them in a little research. I'd say you should have an instrument that's easy to learn and use, and that introduces the students to a good range of the capabilities of a good VNA. It would be good if it introduces them to the importance of calibration, and just _what_ should be calibrated on a VNA. It would be good if it can make s-parameter measurements. The concept of having the ability to make calibrated measurements at the end of a (possibly fairly long) transmission line is very useful. In actual use, I'd look for ways to illustrate that they (all of them) have limitations: there are tradeoffs in the design of a VNA, made with an eye to the intended application(s).

I know that HP published some nice application notes about VNA applications and calibration and accuracy limits. Likely Rohde & Schwarz and Anritsu and others have similar ap notes. If you have trouble finding HP ones, I may be able to help, but they're likely on the Agilent web (somewhere). Also look for articles in the HP Journal...again, I can help if you can't find anything.

Cheers,
Tom

Why does everyone think that PIC is the only microcontroller or the best
/easiest one? Since PIC needs higher programming voltages and not all PC
serial ports provide enough of it, most of the very easy PIC programmers
dont work. I would suggest you use atmel avr's. A nice programmer for it
can be found here : http://www.xs4all.nl/~sbolt/e-spider_prog.html
A freq counter using avr and logic counters is here :
http://www.myplace.nu/avr/countermeasures/
You can find more stuff when using google.

Cheers,
Ronald

While a G5RV is an efficient antenna on 20, and acceptable on many bands, it
is terribly inneficient on other bands due to
the high mis match on the coax. It is easy to check out with Reg's dipole 3
program.

Source record: 28705

Hi.

It uses an FPGA (or CPLD) and a clock (DS1075) for time reference. The parts that i'm using are:

Xilinx XC4010XL-PC84

Dallas DS1075-100

The FPGA has everything, it has 1 sec reference using the DS1075 (working at 100Khz), 5 divisors to select range of measurement, display control and parallel port control.

There are two ways to improve it, one is that I can use the internal FPGA oscillator, but it has a poor precision, and the other it's to use a different oscillator, maybe a crystal oscillator.. it can be of any frequency because that is programmable to the FPGA... that way it would be 1 IC frequency meter.

I will put it the VHDL source in the web with a hand-made schematic, and the PC software. The VHDL can be synthetized with Xilinx Webpack (free download from www.xilinx.com) and to program the FPGA you can use Xilinx Parallel Cable III(schematics for it searching on www.google.com). You can use any FPGA that has enough room to all the circuits, but I think the software can suggest you wich one to use.

All of that can be found at

http://www.geocities.com/hernan_sanchez/

I will put the files there this night (3:00 GMT).

Regards,

Hern&#65533;n S&#65533;nchez

DO be sure to fasten the weight with another rope so that if (when?)
the antenna does break, the brick won't fall on someone's head!

If one or both of the trees is liable to sway a LOT, you can add another
pully to the weight and run the rope back UP the tree to where the
first antenna pulley is; that way, one weight (which probably needs to
be heavier) can handle twich as much sway.

There is already an excellent computerized version of the Cardmatic
available by Signal Systems--Phil Frakes. This machine apparently
works very well and is in use by SND Tubes and AES. So--no need to
reinvent all of this--plus the software is done for you. You can have
your tester converted to this system by Phil and then no cards are
required. I believe he has something on the web about the machine.
The conversion is not cheap, but you are talking about a major amount
of wiring and relays. Plus--a full set of Cardmatic cards is worth
over $500.

I do have a complete card set, and have made a few cards for
people--one hole at a time. This just is not practical. My hand
gives out after two cards. Wendell Hall has a friend with an original
Hickok fixture for punching the cards. I'd like to get that fixture,
but Wendell says the guy won't part with it.

> Not really all that uncommon. A Wheatstone bridge works fine for
> monitoring SWR...transformer-coupled versions...network analyzers...

[not trying to be or sound condecending (:-) I know all that. I was just
trying to help the OP understand this term "directional coupler" from the
ham perspective. In the context of today's *ham* SWR reading devices, having
a current sense resistor is unusual. Besides I am talking about a 1,000
watt full scale directional watt meter. It reads power directly in several
ranges. Supposedly what the modern ones do. So I was thinkin' a resistor
to sense current should be a bit of a surprise. In the 40's they didn't
have the transformers.
I also have a 5-1000 MHz SWR bridge, obviously low power as well. Spec'ed @
40 dB. Very lucky find. ain't cheap.

> you are verrrry careful about the construction.
Yea, Yea. That's one of the points I was making.

> > > You might think of microstrip or stripline as "hammered flat coax."

I'm ok with this analogy, I just had to add my 2 cents.

> (And though stripline is true TEM, microstrip is quasi-TEM
I didn't think the OP cared about this. Also stripline is model-able,
micro strip (was only approximated) by Wheeler & Sobol, when I was designing
it. However, I think the OP wouldn't care about this either.

> > I believe a 1/4 wave is not important here.
> Right...but beware of NULLS in the response at integer multiples of
> 1/2 wavelength,

I was thinking less than 1/4. I won't open it to see how long the
coupled lines are, but my Narda is about a foot long & goes down to .. gee,
I don't remember. Gotta go look tonight. I think 500M

They are pretty usefull things if you can get your hands on a good
one... and have the rest of the equipment to use it. I wasn't trying to
give the OP a tutorial on precision directional coupler design, just some
analogies to hang his hat on. Is the OP reading the rest this??

> > > Typical directional coupler coupling is 20 db down from the main
line.
> In fact, -20dB with 100 watts input gives you a WATT at the "FWD"
> output,

That's why I didn't think it appropriate to say any particular value was
"standard". Get what you want. The physical construction determines the
coupling factor was where I was going as a contrast to the "snake-ed" ham
kind which has a variable construction and therefore coupling.

> > > While not perfect, directional
> > > coupling differences of about 20 db are good enough to warrant the

<SWbeginner@nowhere.com> writes:

>This would be great for me but can it work with LED's. I haven't work with
>LCD displays before and don't know which one works.

There are several LCD display units available commercially with the
LCD (typically 2 x 16 character rows), drivers and temporary memory,
and optional backlights. They are driven by ASCII coded character
digital byte-parallel input assemblies. PIC and Atmel based counters
can output ASCII according to count plus including controllable legends
for whatever purpose, all under the microcontroller internal program.

LEDs are fine for bright displays, good for viewing out of the corner of
the eye to note changes when working on something. Microcontrollers
could be reprogrammed to output sequential 7-bar segment signals for
external temporary storage, such as a latch-decoder-driver IC for one
decade's LED. LEDs are also relative power hogs from the local DC
supply compared to the entire LCD assembly (8 digits will take around
0.6 A maximum at 5 VDC to light 8 LEDs). LCD power drain is in the
microwatt range, the drivers of an assembly taking most of the DC
power. Low power demand is the major reason for using LCDs in
small-battery watches and radio clocks.

LED readout is very legacy in digital circuitry. Many-digit LCD
assemblies aren't so common and appear strange because they
haven't been as widely used for as long a time.

I will suggest perusing the www.aade.com website to see the counters available there. Some are available in kit form and they are simple and elegant, include an LCD assembly for readout. All you need do is hook up a DC power source and check the timebase against WWV.

Otherwise there are a surprisingly large number of websites concerning PIC and Atmel based microcontroller counters along with associated microcontroller program source listings. Any search will turn up dozens of hits. Modifying the existing programs might take up more time than you would imagine unless you have lots of Assembler coding experience.

>simplified comparison with the monimatch and a little info on how they work.

Fine. :-)

I just added some things about directional couplers in general. These
postings are all very public and don't necessarily pertain to one
individual. Sometimes general information is an aid to a reader who
does not post. There's lots more readers than posters in most news-
groups.

Here's some links to couplers and power meters which are current
(checked today to see if they are still there):

http://www.ee.bilkent.edu.tr/~microwave/magnetic.htm

This site has HEAVY theory on - Rectangular waveguide, microstrip
antenna design and analysis, microwave filter design, Lange coupler
design, branch-line coupler design and analysis, directional coupler
design and analysis, 180 degree hybrid coupler design and analysis,
microwave power divider design and analysis. The "design and
analysis" includes an on-line calculator-applet to plug in numbers and
it grunges through the math for the user. It is practically a FREE book
on the basic UHF-microwave passive component region and should
save anyone's wallet to the tune of at least $120 (the old "Matthaei-
Young-Jones" hardcover is more than that now, even after 30+ years).

From the Microwaves & RF magazine archives, there is the February
2001 tutorial "Understanding The Basics Of Microstrip Directional
Couplers" by Leo Maloratsky, pp 79 to 94, a very concise article on a
large subject. Maloratsky worked for Rockwell Collins in Melbourne,
Florida at that time.

For direct SWR measurement using a Bruene detector and using meters
for readout of both forward and reverse power, the QEX article by Paul
Kiciak, N2PK, gives dimensional-construction information on the bridge

for HF and uses AD8307s as logarithmic detectors for both forward and reverse plus op-amp couplers to the indicating meters. I have a PDF that lacks the QEX identifying issue and page that was obtained from another in July 2001, can't supply the QEX issue date or pages.

The Bruene bridge was first used in military T-195 transmitters that became operational with USMC and US Army in 1955...part of a very easy to use HF vehicular Tx/Rx using tubes and long vehicle whips. Collins did the design under contract. A version of the Bruene bridge is still used today in the US military in the AN/PRC-104 backpack 20 W HF radio which has an auto-tuner for the whip. Hughes Aircraft designed, became operational in 1986.

I emphasize measurement methods because a finished coupler or bridge or whatever needs to have something to measure it at lower powers than available on Bird Wattmeters or similar. One of the nicest applications of the Analog Devices AD8307 as a Wattmeter with an 80 db dynamic range is on Thomas Schirrer's website:

http://www.webx.dk/oz2cpu/radios/milliwatt.htm

That one uses only two ICs, the AD8307 and a Microchip PIC16F876. Accuracy of RF power measurement is all up to the AD8307 which can work up past 500 MHz, has direct connections of RF input to the AD8307. The PIC does conversion of AD8307 DC output volts to either Watts or dbm and also controls the LCD panel unit (2 x 16 character integral LCD panel and driver). No other active devices are needed except for the DC power supply. With appropriate programming, serveral different PIC microcontrollers can be used. Several others have copied the same circuit with variations on the case on display legend, as indicated on the website. Simple and elegant. Calibrate once and such will remain, error dependent solely on the AD8307.

>> ...Analog Devices log detector is
> I saw that little bugger in QEX. Pretty cool!

Lots of information on the Analog Devices website for datasheets and application notes on their full line of logarithmic detectors. Why anyone still wants to depend on germanium diode detectors with very limited dynamic range and non-linear detection is beyond me. :-)

Up until about year 2000 I had a wonderful multi-gauge stripper
made in my home town of Rockford, Illiniois, about 1950 (!).
The "recoil spring" (to return the two-handled beastie to open
position) broke and a replacement was impossible. The design
had been sold to another company (perhaps General Cement)
in the 1950s and that company no longer produced it.

For stripping in general I use small diagonal wire cutters (kept
sharp) and, by feel, go part-way through about three places on
the jacket, then gently tear off the jacket. Very no-frills stripping
(of wire, that is). Practice made perfect a long time ago.

The toolbox also has an ultra-simple el cheapo stripper stamped
out of sheet stock, looking like cheap cutters with a single V-groove
on each head, opposed. Very easy to keep sharp but the straight-
side cutter edges tend to nick the wire, especially on stranded
variety. I use that only as a last resort.

For chassis-PCB wiring, I prefer to use solid wire and cut Teflon
sleeving to suit for insulation. No flexibility is needed there and the
Teflon sleeving, although costing more than PVC, is reasonable in
price in bulk (depending on supplier/distributor). The sleeving IS

reuseable (and wires used for short runs) after a project is scrapped
and/or revised.

>> [I'm secretly glad no one remarked on the extra T in 'insulation,' that
>> would be instigation of insulting the insulation installation... :-)]
>>

A rule of thumb says that the screen around an oscillator coils could be 3 times the coil diameter, and Radiotron Designer's handbook, 3rd edition, 1941 says that the screen should go at least one coil radius above the coil. But how far from the chassis should the coil winding start?

Wouldn't you presume one coil radius above the chassis?

I agree with all your points against LED's except they are very simple to use and that's what I need for now.

The displays at the aade.com site are very elegant.
If you or someone can recommend which LCD display to use and a site wich a good tutorial then that would be fantastic.

The whole point of homebrewing for me is to learn how these things work and be able to design and make changes. Otherwise I can buy all the gear on Ebay but not learn anything.

>start?

About the same distance. :-) The old Radiotron book (I have a CD for one of the editions as a keepsake) has charts showing the inductance reduction and Q reduction for various relative diameters. The closer the enclosure, the more reduction of both values. That sould be accounted for in any resonant applications, especially those for tracking as in superhet or TRF front-ends.

The conducting enclosure or shield contains the magnetic field on the coil and, ideally, should have the same clearange from both top and bottom of the winding. It will still work with an assymetric clearance but L and Q are spoiled by the closer spacing.

Toroidal cores are much less affected by conducting enclosures due to the magnetic field contained largely IN the torus' core material.

Then you can go with LS TTL and use a pair of ICs per decade/digit.
A 74LS192 as a decade's actual counter with a CD4511 as a latch-
decoder-driver for the LED...or a CD40110B as a counter-latch-
decoder-driver at a slower input rate (with prescaler as needed to
reach the desired max. input rate). 74LS90s or 74LS290s as decade
dividers for the timebase...plus various NAND gates to select the
count gate times. All of those types figure in to drive LED 7-segment
numeric displays.

>The displays at the aade.com site are very elegant.
>If you or someone can recommend which LCD display to use and a site wich a
>good tutorial then that would be fantastic.

There's over 50 different models and sizes of LCD display assemblies
available, from 1 line of 12 characters to 4 lines of 16 characters. To
use those assemblies, you need to know how to get the sequential
ASCII into them to show on the screen. That isn't simple for a tutorial
or anything else unless you know serial digital transmission basics.
AADE apparently gets their LCD assemblies in bulk to package with
their little frequency counters, have the necessary coupling from the
16F71 program coding.

The bare LCD unit needs special driver ICs since those are generally
of a sort of 3-state waveform needed to clear/energize (make black)
a selected place. Some are only 2-state. Varies depending on the
type and manufacturer. That's why I recommend getting an assembly
of the display and its driver board. A search of the Internet will turn
up several distributors selling to individuals. If the end applicaion is a
counter using a PIC or Atmel microcontroller, then the project website
will have the part number of the display assembly they used.

>The whole point of homebrewing for me is to learn how these things work and
>be able to design and make changes. Otherwise I can buy all the gear on
>Ebay but not learn anything.

Understood. I'm still putting things together and still learning, still having
fun with all these new things even though I've been in the electronics and
radio racket for quite a while (over 50 years).

You can get the basics of frequency and period counting from the Agilent
website from one of their application notes. There's several other sites
by individuals explaining basic counting. To make an IC counter using
two ICs per decade, a latch-decoder-driver is needed to hold the binary-
coded-decimal 4-bit state out of the counter after a count and then
decode that BCD to light the appropriate LED segment of a 7-bar segment
single digit display. The whole thing needs a timebase section which
is a crystal oscillator (usally at 10 MHz to beat against WWV for
calibration) followed by dividers (usually decade counter ICs running
continuously. The selectable timebase signals are used to gate the
counter's input for frequency indication with the gate opening time in
increments of 10 such as 1, 10, 100 mS, 1 or 10 Seconds for minimum
count digit display of 1 KHz, 100, 10, 1, and 0.1 Hz respectively. To
mesaure period, just reverse the count input and timebase gate control
so that you count the timebase frequency with the gate supplied by the
input signal.

To connect this to the outside world, you need a wideband amplifier to
help raise the level of the input signal, then a shaper such as a Schmitt
trigger gate or inverter to make the signal have nice, sharp leading edges
to apply to the count gate. With all that digital stuff there needs be
attention paid to bypassing the supply rails, but that is easier since all
the components can be running at the same + supply voltage; +5 VDC
if "74" chips, +9 or +12 or +15 if CMOS equivalent function types to TTL.

There are still lots of digital ICs available for this kind of project and
the
datasheets are all downloadable from the Internet. Putting them all
together is not an easy task but it is repetitious to the degree of the
number of digits to be displayed. The number of digits to be shown will
put a rather surprising large current demand on the supply for a maximum
digit indication, "8" in case of a 7-bar LED, all 7 segments on. 140 mA
per decade at 20 mA per segment. With 6 digits that is 840 mA max.
LED supply drain can go from 240 mA min. for all "1" to 840 mA max. for
"8" with 6 digits...can be fair jump in load change on the internal supply.

In going for a discrete IC per decade style, the overall task is a strenuous
one. To begin, it is much easier to get a KIT if possible, or one of the
little AADE counters (which have some user interconnects necessary).
Once you have it built or installed, you have a "learning" device and can
go back into its guts to find out how it works. For PIC or Atmel based
counters, most "learning" takes place in following the program source
code; the hardware itself is rather simple, just a handful of parts.

A frequency (and period if desired) is the most precision instrument you can successfully design and build in the home workshop. Only one circuit, the crystal oscillator, sets the accuracy, typically better than 10 parts per million beat against WWV. The rest is enabled by digital ICs off-the-shelf at relatively low cost (less than $1 each, average). It does embrace a number of electronics technologies not necessarily those of old radio. "Simple" it isn't and that includes the micro-controller types; those have most digital hardware functions implemented in software. Experience in designing, building, and working with them will come in handy on such future projects as PLL or DDS frequency control, DSP, and many other subsystems of modern radios. If you bother to study them in detail you WILL learn a lot of new things, but there is considerable "home work" in that self-assignment. Good luck and enjoy the course! :-)

The old IBM key to card punches that I have seen (and scrapped) were
the model 19 and the model 29. They were small steel desks full of
mechanical and electrical parts that no one wanted, so they were
scrapped for the steel frames and made into small work benches.

The 'at least one radius' thing applies at both ends. The magnetic field
of a solenoid is axially symmetrical.

Imron is very special and pricy stuff. It requires a hardener and can frost up your lungs if you don't use the proper breathing apparatus. In other words, you die. It costs over $100 a gallon.

I simply cannot believe that anyone would recommend this paint in this newsgroup for painting a bit of metal. Do you use rocket fuel in your car as well?

You paint aluminum like any other metal.

It seems that the Internet has invented something that could never have survived previously - the instant specialist. This person repeats any and all gossip, rumors and inuendo as if it's fact, with no experience whatsoever.

I have never seen the punching fixture, but think it consists of a
number of punches with a plate and die that matches the plates in the
tester. Punches are added or removed, depending upon whether a hole
is to be punched in a certain location. When all punches are in place
the (guessing) lever is pulled and a cam drives the punches through
the card into the die. Even this method is pretty darn slow. You
would be working for a long time to make up a set of thousands of
cards. Now there was a guy selling some cards on Ebay a year or so
back--he was in California. I don't know if he has any cards left.

better make that a model "026", and "029". There was also a model "129".

the 026 and 029 were distinguishable by the _round_ keys that stuck up from
the keyboard, like a forest of dowels. The "129" had a contemporary-looking
keyboard. with a grid of square keys.

>mechanical and electrical parts that no one wanted, so they were
>scrapped for the steel frames and made into small work benches.

I don't know anything about the cardmatic, but if it uses a 'standard'
Hollerith-style punch-card format 'card', then I know where _lots_
of "surplus" card-maker devices would be available. _Everywhere_ that
governments used "punch-card *VOTING*MACHINES*". You could even make up
a 'ballot form' that had a crib-sheet on it for what each hole in the
card meant. <grin>

1192. LED PIC based counter?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-11 13:47:22 UTC
From: Dale Parfitt <par@parelectronics.com>
Message-ID: <KnqWb.13009$%X3.773@nwrddc01.gnilink.net>

I've gotten the best results by first washing with a strong detergent,
drying, and then using fine steel wool (0000 grade), wiping with a tack
cloth to pick up any steel wool and other dust, and then using a zinc
chromate primer.

1194. Re: Recomendations for a VNA

I just got through building up the VNA that Dale mentioned. Kit price is 250
dollars, plus 5 dollars shipping in the USA.
Right now, I am etching the power supply board, and I hope to have the unit
up and running later this afternoon.

Do youse guys in the US not have Hammerite paint? That's what we
mostly use here in Britain. It's top-notch stuff. Needs no priming or
special preparation at all; tough, durable, corrosion-resistant finish
suitable for exterior metalwork in all climates. Good range of colours
finishes and textures. And it's non-toxic. The only thing you need is
the special thinner (only for cleaning brushes or spray equipment -
not the application part).

I have bought it in the US. It is tough and good looking.

Most paint bonds well to aluminum oxide, if it is completely clean. I think the best oxide for paint adhesion is a porous chromate anodize, but thermal oxidation is very good, also. If the object can take the heat, Wipe it with paint thinner, let dry, and bake it in a hot oven (450 F) for an hour or so to evaporate or oxidize all traces of surface oil and provide a good surface oxide. Do not touch it with skin before painting.

I said it was pricey.

As for the danger, lots of things related to amateur radio can be dangerous
and can kill you.

Working on a KW amplifier is dangerous and can kill you if you don't know
what you are doing.

Doing just about anything with a tower is dangerous and can kill you if
you don't know what you are doing.

The paint, just like the tower, comes with safety instructions.

If someone is dumb enough to ignore safety instructions, well...

> I simply cannot believe that anyone would recommend this paint in this
> newsgroup for painting a bit of metal. Do you use rocket fuel in your car
> as well?

> You paint aluminum like any other metal.

The poster didn't ask HOW to paint aluminum, he asked about tough, long
lasting paint. Imeron is tough, long lasting paint.

> It seems that the Internet has invented something that could never have
> survived previously - the instant specialist. This person repeats any and
> all gossip, rumors and inuendo as if it's fact, with no experience
> whatsoever.

What makes you think I have no experience with Imeron?

Isn't it a bit condescending of you to decide what is too expensive or too
dangerous for someone else to use?

I credit the original poster with enough intelligence to make his own
decisions on that.

in UK there is a paint called Hammerite, you can get both "crincle"
{similar to the finish as used on the AR88} or smooth. cost is about 3
quid (six dollars US) for a small can or for a spray cannister, the
latter is easier to use but has less paint. It sticks well and can
give a very professional finish.

It's available here. Their web page recommends use of their primer for
aluminum.

I've had mixed success with Hammerite on aluminium (alloy). It certainly covers well, but in the longer term it tends to flake off aluminium surfaces that had not been extremely well cleaned and de-greased before painting. Since the object in question was a 12-yagi antenna array, scrupulous cleaning of every square inch was not a practical option.

After a few years outdoors, it seemed that the Hammerite was bonded only to itself. The slightest tap would knock off a large flake, exposing bare metal with no trace that the paint had ever been truly bonded to it.

The best primer I've found for aluminium is a solvent and epoxy based formulation called Bonda Primer, made in the UK by the Bondaglass company that makes various kinds of fibreglass materials and car body fillers. It is a red oxide primer, presumably intended mainly for steel bodywork, but it really does bond to aluminium. After drying overnight, it forms a very tough skin that will take any top-coat - including Hammerite - and it will *not* come off.

I don't suppose Bonda Primer is available in the USA under that name (it's hard enough to find in the UK, from a few independent auto parts shops), but you could try to find a similar solvent and epoxy based red oxide primer.

A number of years ago I picked up a pint of an acid, from NAPA
Auto Parts, used to clean aluminum for painting.
Once clean, I use epoxy appliance spray paint from the local
hardware store.

An alternative might be anodizing, which is a very durable and
corrosion resistant finish.

Some outfits which do anodizing will add your part in with a batch of
other things with the same process, and it could be far less $$ than
you think.

Any surface treatment, anodizing, paint, or whatever: surface
prep/cleaning is the key to a quality finish.

Happy trails,

Hallo Eddy.
Well i give them a call today and yes they were verry helpfull.
The man i spoke to gave me a site where i could download several
complete manuals. Not the BE-5A manual but manny others.
He alsow say that when i have anny questions he will do his verry best
to answer them. I totaly did not expect this kind of help from a
company that build an sell broadcast transmitters. They dont work
with the CX5000 annymore but the 3500 / 7500 / 20000.
So now i have all the diagrams which they are produsing now.
They work with a folded half wave coaxial resonator which is made to
resonace with a pipe into this half wave resonator. This adjusting
pipe can be lifted up or lower down to make the line half wave coaxial
resonator resonate.
They output is done by a pick-up resonator near the plate coaxial
resonator line. The folded half wave coaxial resonator is in a cavity
which forms together a 55 ohm coax-line.
The Harris company has a total different design which you can see on
www.ghz.it
I'm sure when You see the photo's You will understand.
The design makes it possible to make the cavity much smaler.
This is the one i'm gonna make. I allready did some (un-power'd no
voltage)testing. Looks pretty good. Nice sharp dip in the plate
resonator.
Maby in the future i will alsow build the B.E design.

Eddy thank's for the phone number of this company.
It realy helps out to see all those designs to make your own.
We will speak again. Greetings from holland. Onno.

That's the cyanide-based one, isn't it? He'll need a full-face,
filtered respirator with an air pump and inlet at least 30' away or
risk a sudden and very unpleasant death. Seems a bit OTT 2 me.

Why do you want to paint an antenna ?
If it is going to be outside, you may need to check out the airplane paint.

>important factors here- LCD displays are not an option.

A problem there is finding an LED numeric display with low current
per segment or a driver capable of higher peak current for sequential
strobing of an array of LEDs. The only thing that I could recommend
is the miniature LED array with integral magnifying lens and filter that
HP made for their first scientific calculator, the HP-35.

In the HP 1979 Optoelectronic databook, the 5082-7200 series and
5082-7400 series have varying numeric character assemblies from
2 to 16 digits. The 5082-7240 is an 8-digit assembly "capable of
being driven by MOS circuits" (according to catalog text, apparently
in reference to calculator use). Average per segment current is
about 0.5 mA and peak current (for strobing array) is 5.0 mA. The
character height is 2.59mm by 1.52mm wide but magnified by the
integral plastic lens. I've stared at that HP-35 calculator display
long enough without eyestrain from the appearance (only headaches
from results not meeting expectations). Brightness is okay to use
in a well-lighted office environment but gets a bit dim outdoors in the
shade (such as a QRP outing?).

I don't know if they are made any more, couldn't get through the
Agilent-HP site to find them. Someone makes those little LED
numeric arrays now, used in hand-carried frequency counters.

A PIC would strobe segments and the program could be adjusted
to optimize the on-time duty cycle for a particular segment. In using
unmagnified LEDs, the average segment current is around 5 mA
minimum for sufficient brightness but that is variable depending on
the molded-in filtering for various colors (attenuates brightness).
Strobing would require higher peak currents.

Cyanide based?

Most of the better aircraft paints (for metal; fabic is different) are
polyurethane enamels. Polyurethane mists require masks, but an air
pump 30' away, hardly.

Your VERY welcome Onno!
Glad to help. I have worked with a pair of those BE-5A transmitters for the better part of 18 years and they are a very "hearty" design. I am sure the finished amplifier will be good for you and something to be proud of. Good luck and let us know how it goes....Eddie

Hi Paul,
I just finished it this evening.....it is a
good piece of equipment, and worth the money. Tomorrow, I will do more
in-depth testing. It appears to have resolution to 6 digits, which is good.
It consists of a pair of 9851 DDS chips, with a 1496 being used as a direct
conversion detector. I think I am going to build another one, so I can use
one at home and one at work.

Pete

>polyurethane enamels. Polyurethane mists require masks, but an air
>pump 30' away, hardly.

According to the MSDS, some of the Dupont Imron paint formulations contain an isocyanate, or use an added isocyanate activator/hardener. This also seems to be true for some of the two-part "linear polyurethane" finishes from other manufacturers, as well. The isocyanates can cause a permanent sensitization of the lungs - a chemically-induced asthma. Think "Super-glue fumes, in giant industrial-sized portions" and you're probably in the right ballpark.

For these formulas, the MSDS specifies the use of a positive-pressure, supplied-air respirator. Filter-type masks are not adequate.

It looks as if some of the Imron paints don't use isocyanates, and an air-purifying respirator with organic-vapor filter cartridges is stated to be sufficient.

http://www.bronkalla.com/upkeep/spray_imron.htm is interesting reading, written by a boat builder/refinisher who used used a clear Imron above the waterline.

Sure looks as if this stuff is something to be _very_ careful with... read the MSDS, follow the instructions, observe all precautions, etc. The idea of shopping out the job to a local body-shop which is already set up for it is a good one, if you can find one in your area.

>Why do you want to paint an antenna ?

To keep the neighbors happy. Southern England is not the land of wide
open spaces, and this antenna filled the width of our long, narrow
garden.

Don't worry, I didn't paint the yagi elements; but all the support
framework had a coat of Hammerite green.

I wasn't trying to make the antenna invisible - that would have been
impossible - but showing the neighbors that I was making an effort. In
that respect, the paint job worked and was appreciated.

Thanks, Pete. Resolution is one thing, accuracy is another. Do you
have a proprietory instrument within calibration to compare it
against? I want to believe in this kit. If it works as advertised then
it's a significant breakthrough for those of us who feel reluctant to
part with 20,000 quid for a piece of relatively infrequently-needed
test equipment! Please report back here when you've had the chance to
check it out properly and let us know how it performs...

N2PK's website (www.qsl.net/n2pk) gives exhaustive information about measurement accuracy, standards and comparisons with professional VNAs.

When used correctly (a necessity for any VNA), N2PK's instrument is so accurate that he had to go to extreme lengths to find any real differences from commercial equipment. For example, the measured signal magnitude tracks a 'standard' step attenuator to better than 0.1dB over a >90dB range... but which is in error, the VNA or the attenuator? At those levels of performance, it's almost impossible to tell.

Bottom line: you'll hardly ever need to worry about accuracy as such, only about using the instrument correctly.

The only minor drawbacks are a small amount of thermal drift (because this is a DC-coupled system) and the possibilities of responding to DDS harmonics and spurs; all of these are very thoroughly documented.

>If it works as advertised then
>it's a significant breakthrough for those of us who feel reluctant to

Having had one running for about six months, I can confirm it's excellent. Far from being infrequently-needed, it has become one of those instruments I couldn't possibly manage without!

Read the documentation and you'll see exactly why.

Hi Tom,

Thank you for sending that article, it made it fine.

It is quite helpful and gives detailed instructions, I might actually buy that whole book..

I also want to thank all the other posters. Some of the discussion were definetly over my head but as time goes by I might understand this or that detail better. First I need to get my hands on one of those SWR meters (I hear the old URM 120 are quite good and rugged, if I don't built a meter myself that might be the way to go) and gain some experience, I like to learn the theory hand in hand with practical experiments.

Paul, what part of the comparison between my Boonton and the N2PK VNA do you have a difficult time with? Or for that matter, the comparisons with Chip Owens HP 5783C? The accuracy is primarily limited by the quality of the OSL standards used in setup, and the experience of the user in establishing his/her reference plane.

I did play with it today, sweeping a couple of filters. The unit is amazing!
I understand that one fellow in England is developing Windows based software
to control this unit. I am pretty excited about that.
I don't have any suitable transfer standards for checking the accuracy of
this instrument, but the designer has done a very good job of characterizing
this unit. See the following posts.
One more thing.....I think you would be very happy with this unit.

Well to answer the replacement question - according to GE Industrial Tube Products Guide - (Dated 9-79)

You can replace an 829 with an 829B.

You can replace an 829A with an 829B or an 3E29.

You can only replace an 829B with another 829B.

Why? I don't know, that's what GE says.

Now what an you use an 829B for? Well I got one, it was a spare from a GE 6m Prog Repeater our club had on the air. The replaced it with a nice Moto. The Prog was up for grabs but no one wanted it and was about to be hauled to the landfill so I took it.

It lasted about two days in my house working fine. Then I put it out of it's misery and parted it out. It had lots of juicy power transformers, tubes and sockets, XTAL holders and so on. Most ended up in other projects or repaired rigs except for the 829B.

What to do with it ???

I decided to build a one tube 40 Meter CW transmitter.

Nothing special about that - all of us have built 6L6's or 117L7GT, 6V6, 6C4, 6GW8 or you name it peanut whistlers. Nothing more than an oscillator connected to a string (antenna) blasting out a few watts.

But how about a SINGLE tube transmitter pumping out 100 to 115 Watts !!!

With minimal parts count to boot!

I got the idea from QST - June 1940 (page 26) in which Fred Sutter W8QBW describes a transmitter using -TWO- 6L6's in push-pull supposedly outputting 100 watts to an end-fed Zepp.

I'd take the 100 Watt claim with a little grain of salt... but it's still not too shabby for 12 parts and 2 tubes not counting the power supply.

The 829B can replace the two 6L6's and the circuit can be adjusted accordingly. The output tank circuit will be PI instead of link which was common back then. I also have a nice power transformer that looks like it can do 700 mils at 750 VAC so I have plenty of head room to crank out more power if it can handle it and the XTAL doesn't shatter.

I'll use forced air cooling because the 829B socket is already designed for it. Was gonna go with a fancy blower but I noticed the XYL is not using the

small Dirt Devil handVac I gave her for her birthday. Will cut a small hole in the chassis and placed a PVC pipe and attach the air hose to that. RCA Manual says the MAX glass temp is 235 F so hopefully, the plastic vac can handle it.

For a Glass Chimney, I took a drinking glass and cut off the bottom with a glass cutting wheel. I was rinsing out the dust in the sink when she spotted me. I told the XYL I had just taken out the glass from the hot dishwasher and poured a little bit of cold water and the glass cracked and the bottom fell out. I hoped she didn't notice the ends were nicely smoothed.

You should have seen her face. Classic...

It's the same look I get when I bring in another hamfest surprise and promise it's the last radio I'll ever buy because my radio collection is complete - excuse.

Well anyway - A single Tube 100 Watt CW Transmitter - that's my 829 project.

Have all the parts - now waiting for the weather to warm up so I can get to work in the Garage.

You just know if she sees that tube chimney and her Dirt Devil, I might just have to sleep there too.

-Biz WDï¿½HCO

I posted a picture of my 829B on alt.binaries.pictures.radio for those who have never seen one.

I shall. And thanks for the info!
I didn't realise you'd bought the kit. Did you have to have it shipped
over from the States? I assume there's no outlet for them here, as yet
at any rate. What's the UK price inc.shipping? (Just in case I can't
find those details on the site).

At the time, there wasn't a kit as such, but the parts cost about ï¿½100
in total (not including the DDS ICs, which Analog Devices generously
supply free to amateurs as 'samples').

However, certain parts are only obtainable in the USA, so people in
Europe are getting together to buy in bulk. I don't have any specific
information about that, but a mailing-list is to be started shortly
(wait for the announcement) so that will be a focal point for people to
co-ordinate their buying.

> yours for. What makes it so indispensible?

When was the last time you needed to know a capacitor value AT the
frequency you're going to use it at? (the "C" minus the "L" of the leads)
Or the passband of a filter and it's IL and it's skirts and it's blowby and
it's group delay and it's terminating impedances?
Or needed dual high level isolated oscillators to make Ip3 measurements on a
receiver or transmitter?
Or have a precision sweep generator and trigger for a Spectrum Analyzer?
Or needed the inductance of an inductor AT the operating frequency? (The "L"
less the "C")
Or needed the series and parallel resonant frquencies of a crystal and the
Rs of same and it's "Q"?
Or needed the "S" parameters of a small signal transistor?
Or wanted to know the impedance of your antenna at the shack end of the
coax. Or, if you were smart enough to log the length of coax when you
installed it, the impedance AT the antenna?
Or needed the Zo of a length of coax?
Or the gain of an amplifier over it's frequency range and it's 3 dB corners
to the 0.01 dB?
Or needed a quadrature signal source to be the LO of that new I-Q receiver?

Or-or-or

It's a lab in a box.

tried some amateur rubbish the other year, but the problem with
amateur constructions is ususally that you cannot make two units which
performs similarly, and it is difficult to tell what decides the
impedance. If somebody have another opinion I'll be pleased to hear,
it is not 1% accuracy I am after, 10% is good enough and that the
readings are successively the same for the same conditions. Put some
info about some simple couplers you can make on my site, you'll find
it with google search for "Bird Model 43 patent description"

Well, I forgot to say that I would leave the top side open, so it is
somewhat more distance from the hot side of coil to the metal surface
than in the bottom, but thanks to all for the reply

I have a boat at a marina,I cannot receive any AM radio using Marina
power.
The audio is one continuous buzz across the dial.
A battery operated radio is ok
FM reception is ok.
I took a scope down and looked at the A.C. waveform, the signal has no
visable noise riding on it, however the wave peaks are flatened. It is not
hard
clipped, it just doesn't have a nice round peaks.
I'm looking for suggestions on how to filter the AC so my
radio will pick up AM.

Thanks
Mike

Hey! I think I have some of those. Since I'm never going to use them, I suppose I could part with them.

But first the obligitory assesment of assumptions: Why are LCD displays not an option? Could you drive an LCD from your PIC? I've seen info on this from the LCD manufacturers; it looks quite doable from a PIC.

The URM 120 and their variations are very good, especially for the money.
Think I payed about $ 150 for one at a hamfest. I was very luckey in that
it was new in a sealed box, never opened and was about 10 years or so old.
Someone had alot of them in a truck. It came with 3 plug in units and goes
from about 3 to 30 mhz up to 1000 watts and up to 1000 mhz to 500 watts.

I was wondering that myself. It's a whole bunch lower power than LEDs,
which seemed to be a requirement, and the circuitry is a pile simpler. The
one requirement he did have was "durability" that maybe you could argue LEDs
had a leg up on. Well, maybe with those teeny LED displays you could keep
the size smaller than an LCD, but I suspect you would more than make up for
it in drive circuitry, unless maybe he's thinking surface mount.

Oh, and driving an LCD is a piece of cake from a PIC.

Is there a simple relationship between a meters internal resistance and its sensitivity (ohms per volt).

Maybe this is trivial but I don't see it.

>from the LCD manufacturers; it looks quite doable from a PIC.

You are asking the wrong person. I was responding to the person
saying "LCDs are not an option."

An LCD display assembly can most certainly be "driven" (input the
ASCII code for the character) from a PIC. That is how nearly all of
the little wattmeters and frequency counters are arranged.

Actual DRIVE for an LCD takes a different waveform for most LCD
panels. Some are 2-level, others 3-level in their waveform voltages.
Research the LCD display alone, without the local memory and
scan-drive hardware. That part is not as straightforward as it looks.

A PIC PROGRAM normally scans through an internal register
content and outputs based on that. Usually there is a small conversion
operation to change the code from 4-bit numeric to 8-bit ASCII. That
scanning-and-outputting part of the program can easily be changed
(if you know how to write with the free PIC development program) to
"strobe" an LED array, segments versus character position.

If you don't know how to change an already burned-in PIC, then you
must have some sort of outboard local memory to hold 4-bit chunks
of numeric data...or convert from 8-bit ASCII to two 4-bit BCD in order
to drive a 7-bar segment decoder-driver that CAN drive a numeric LED.
That requires more ICs, one decoder-driver per numeral. Average power
to light the LED is about the same for any given brightness whether it
is driven on a DC basis or strobed segment v. numeral.

NONE of the above is "trivial" nor any sort of "cake" if you've never
worked with microcontrollers or their development systems before.
Almost ANYTHING "doable" can be done but development time and
resulting learning curves are hard to fund at the home hobbyist level.

For example, I've been working on inventing anti-gravity. Something
keeps holding the project down ...

Thanks to the US-Europe time difference, Harold has left me very little
to add this morning!

We could also think of it in terms of the other instruments that the VNA
can replace - or beat, because it gives full vector (R-X etc)
information. Using only its reflection functions, the VNA can replace
all of the following: an MFJ, Autek or AEA computing antenna analyser;
an LF LCR bridge; a Q meter; an HF R-X impedance bridge; and an HF
return loss bridge.

As Harold pointed out, the twin DDS signal sources can replace an HF
sweeper or a medium-quality HF signal generator - or two of each, if
necessary.

The transmission measurement functions - magnitude and phase, with a dynamic range of at least 90dB - are something I just didn't have.

Several months ago, Harold described an excellent practical example of designing and building a crystal filter. This goes in five steps:

1. Rough out the design using available software.

2. Take a pile of cheap crystals and measure their individual characteristics, on-frequency, using the VNA. Select the best ones for the filter you want to build.

3. Refine the filter design according to the actual component measurements, and use simulation software to predict how it's going to work. Adjust other component values as required.

4. Build the filter. There is no alignment - steps 2 and 3 replaced all that.

5. Use the VNA to confirm that it works exactly as predicted. Have lunch.

You can see those results in the VNA documentation.

This is the professional approach to RF design: compute, measure components, compute again, and build... and it *will* work, because you've left almost nothing to chance. Until now, this approach had not been open to amateurs because we didn't have the necessary test equipment. To me, that is the real power of this instrument.

For some years, I've been trying to develop this approach, but have had to rely on the goodwill of a friend who could make measurements using his lab VNA at work. But obviously there have been limitations on the kinds of things that could be measured - they had to be small enough to fit in a briefcase, and they had to be completed to the extent that they were plug-and-play - so there have been no antenna measurements, and no measurements on work in progress. I'm free from those limitations now, up to at least 50MHz... and the way is being opened to make equally good measurements on the higher amateur bands.

Meanwhile my friend has noticed that he won't have access to the lab forever, so guess what - he has built himself an N2PK VNA too! Like N2PK, we're struggling to identify any significant differences in accuracy between the two instruments.

A compact, lightweight and inexpensive VNA also opens up completely new possibilities for field measurements that even a commercial VNA cannot make, because it's too big, heavy, delicate and valuable to be moved out of the lab.

When the weather improves, I plan to take the N2PK VNA outside with a laptop and a small battery pack, and to do some really detailed antenna work. Of the three objects to be carried around, by far the smallest and lightest will be the VNA.

I hope that gives you a real picture of the new possibilities that are opening up.

The higher the resistance, the lower the operating current, but there
is no simple formula.

You need a current limiting resistor in series with the meter, and a
known supply voltage. Start at the maximum resistance, and slowly reduce
it till you have a full scale deflection. Disconnect the voltage, then
measure the total resistance of the meter and adjustable resistor. Then
use Ohm's law to determine the meter's sensitivity. Its simple and only
takes a couple minutes to test. Use a low voltage, and it is a good idea
to have different variable resistors to put in series. Start with a
higher value resistor than you think you need, so you don't damage the
meter, and work your way down. I use an expensive, six decade resistor
with an adjustable regulated power supply. I can adjust the resistance
in steps, from zero ohms to one megohm in one ohm steps.

============================

Yes. Couldn't be more simple.

It is the internal resistance of the meter divided by the voltage range the
meter is set to.

When the meter is at full-scale deflection the current flowing through the
meter is always (Voltage Range) / (Ohms per Volt).

The internal resistance of the meter, on any voltage range, is the
resistance of the moving coil plus the series meter-multiplying resistance.

No.
>
> Maybe this is trivial but I don't see it.
>
Not trivial at all. The internal resistance of a meter depends on the
type of meter (D'Arsonval, moving iron, electrodynamometer, etc.) and
its design.

As a simple example, imagine two identical 0-1 mA D'Arsonval meters.
Now replace the springs in one of the meters with new ones that
require more force. The meter with the "stronger" springs will need
more current for fullscale deflection even though it has the same
internal resistance.

There *is* a relationship between a milliammeter's fullscale reading
and the ohms-per-volt when it is used with a series resistor to make a
voltmeter.

Ohms-per-volt = 1/current for full scale deflection (in amps)

So, when used with the appropriate series resistor(s):

a 0-1 mA meter will give 1000 ohms-per-volt
a 0-100 uA meter will give 10,000 ohms-per-volt
a 0-50 uA meter will give 20,000 ohms-per-volt

etc.

Think "Ohm's Law." The meter movement responds to a current. To read
voltage, you put a resistor in series with the meter movement so that
V(full scale) = R(total)*I(meter, full scale). R(total) is the sum of
the meter's internal resistance and the external series resistor. So
a 1mA meter movement always gives 1kohms/volt, and a 20uA meter
movement gives 50kohms/volt.

Cheers,
Tom

Dig around for some of the "software radio" projects.

http://www.gnu.org/software/gnuradio/gnuradio.html
http://ourworld.compuserve.com/homepages/jmitola/
http://volodya-project.sourceforge.net/SR/sr.php

There are plenty of others.

Basically, you take the IF signal, bandpass filter it down to a
reasonable bandwidth (as required to cover whatever modulation you're
dealing with), and then digitize it. The digitizer needs to have
enough bits of resolution to handle the range of IF signal amplitudes
you're expecting to see (adding an AGC in front can help matters a
lot), and needs to run at a sampling rate which is greater than twice
the IF bandwidth. You don't have to run the ADC at twice the sampling
rate of the IF signal frequency - just at twice its bandwidth
("undersampling").

Then, pull the data into your CPU and use FFT, lapped transforms,
wavelets, or whatever you want/need to do the demodulation.

>I have walked the marina and the noise on my portable radio gets loud
>when I hold the radio close to each power pedastal.

That sounds, then, as if "hash" from other peoples' battery chargers, switching power supplies, and perhaps the dock lighting systems is getting back into the power mains. Not terribly unusual.

Corcom, Delta, and other manufacturers make modular RFI/EMI filters which you might be able to use. They're usually built into a sealed metal can; they usually have three leads or push-on tabs for connection to the incoming power (and ground) and a pair of leads or tabs for the filtered AC power. I've bought them at local electronics-surplus stores, hamfest fleamarkets, etc. for a few dollars each.

One such is http://sales.goldmine-elec.com/prodinfo.asp?prodid=6379 - a 10-amp LC-type line filter, which they normally sell for $5 and have on sale for $2.95 (plus shipping of course).

You could wire this (or a similar one) up in a metal or plastic box, with a line cord, a duplex outlet, and a circuit breaker or fuse, and have yourself a pretty nice little line-noise-reduction device.

It might not be a bad idea to add some ferrite beads around the wires, as well, to help attenuate the higher-frequency RF noise which might be present.

1263. BPL WILL KILL HF HOMEBREWING IN TWO YEARS!!!

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-14 03:20:38 UTC
From: The Eternal Squire <eternalsquire@comcast.net>
Message-ID: <6Z6dna9eYLmaELDdRVn-hA@comcast.com>
Source record: 28550

Hello, everyone.

Today, the FCC has decided to allow the manufacturers of BPL the ability to regulate
thier emissions under Part 15 so that they do not interfere with other services on the
HF bands (2 Mhz - 30 Mhz).

Given the way we have all percieved business to operate to benefit the stockholders
rather than the public, it seems to me that the demons of the underworld would sooner
be able to enjoy ice skating, than for BPL to be willing to police itself.

And, as you well know, FCC Chairman Powell is a thirty-something Bush political
appointee and an ideologue of the first order. He has sold the soul of Amateur Radio
down the river, all in the name of business above all other things. He is an examplar
of all that is presently wrong with the Bush administration.

I would strongly recommend that we all vote a Democratic into the White House, just
so that said person can replace Powell with someone who will let us live.

In the meantime, sell your gear boys and girls, because Ham on the HF bands is about
to go QRT from massive interference.

The Eternal Squire

1267. Freq-Mite on regenerative RX?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-14 11:38:42 UTC
From: n1jpr@hotmail.com
Message-ID: <95a201e0.0402140338.70f2e0c9@posting.google.com>
Source record: 28554

I am putting together a regenerative HF receiver, and I am considering frequency readout options. Did anybody ever try the Small Wonder Labs FREQ MITE on a solid state regen, i.e. a radio generating just a little RF?

I guess the challenge is feeding it enough RF (~ 0.2V, high-Z) without taxing the detector too much.

Should a pickup inductor in the vicinity of the tank circuit be enough to provide the voltage, or should I plan to add a RF amp?

TIA

Wow
I suspect not much would survive that sort of fall
My counter at http://members.iinet.net.au/~richardh/VK6BRO.htm
takes less than 10 mA
The LCD module is probably as rugged as a LED setup, particularly if you
have to mount individual displays and drivers opn a board
Unfortunately I have sold all the current boards but the software and
circuitry is there.
It uses a AVR rather than a PIC

At first I thought you wanted a counter, but it sounds more like a frequency display for a rig is what you are looking for.

If you're madly in love with LEDs, you may want something like that one digit counter that I think was in QST a few years back. Understand that LEDs are current hungry and require relatively complex support circuitry compared to LCDs. You can reduce both of these by cutting down the number of digits. You can also add some complexity, either in software or circuitry, to help with the current drain, but finding something that will likely work with your radio is improbable .. to get the combination you are going to have to do some of the design work yourself. You will also be challenged in trading off the current for brightness. I suspect (can't say I know for sure) that making an LED display work at low current at a brightness level you could use outdoors in the daytime is going to be something of a problem.

That being said, what about something like Dave Fifield's AFA or Dave Benson's Freq-Mite? This gets you way smaller and lighter than your LEDs, and certainly no less durable. And the current consumption will be orders of magnitude less than even the most carefully implemented LEDs. You don't get the warm, red glow, but you get the frequency in a fraction of the size/weight/current. And for twenty bucks you avoid the whole design/parts procurement exercise.

..

Au contraire!

Well, I suppose if you are scared to death of solid state electronics and computers, then perhaps it's really hard. But in this day and age a huge fraction, bordering on most, amateur radio projects involve some sort of microcontroller. This isn't some comspiracy, they make the whole project simpler, less expensive, and more flexible.

Granted, there is a learning curve if you've never done it before, but I would expect that someone who wasn't totally terrified could learn enough to make the sorts of changes he might need to an off the shelf project, build the programming hardware, and get the project working in less time/effort/money than simply getting a reasonable number of LED digits wired and driven!

Here in UK , like probably elsewhere in the world, FM stations need to be seperated 200Khz to avoid mutual inteference. A good RX ought with good IF filtering ought to be able to seperate two 200 Khz spaced FM signals I think.
But of course stations are only 100Khz apart so it nigh on impossible to seperate stations under these conditions as far as I know.

Well, if filtering won't sort out the problem, can you seperate the stations any other way? Can you make a circuit that responds only to the wanted station when it is just fractionally stronger than the unwanted station? That's the only thing I can think of, apart from antenna solutions. Do we have technology these days to do what we thought was impossible in this case?

>Well, I suppose if you are scared to death of solid state electronics and
>computers, then perhaps it's really hard.

Not I. Made my living, paid the bills for over four decades plus using,
designing with semiconductors. :-)

Try a dose of realistic thinking in terms of hardware, based on the
time available for hobby projects. Time. That most precious of all
personal commodities.

Programming a microcontroller is not trivial. It requires a new skill,
of outlining a sequence of events governed by decision points of
states, of (at least) being familiar with instructions/commands
recognized by the micro. While the PIC development program is
free, the ability to use the program is not automatic in download.
One MUST become familiar with "Assembler level" programming, of
including every single sequential command and decision point needed
by the program application. Having done that sort of thing primarily
for hobby purposes for over two decades, I find it both fun and
fascinating in total control of a micro's actions. My only complaint
there is that there is no standardization of instructions between
manufacturers...the "dialects" require small learning curves each time
there is a switch of micro families.

The most convenient was to apply a microprocessor or micro-
controller is to get one with the program already burned in. Saves an
enormous amount of development time...but does not do any good for
personal programming experience, only in the installation of the micro.

It's hard to beat the AADE unit (available for any conversion scheme,
direct- to triple-conversion) for applying a relatively cheap ready-built

to a frequency indicator. www.aade.com

>But in this day and age a huge
>fraction, bordering on most, amateur radio projects involve some sort of
>microcontroller.

Yes and no. :-) That depends on the source of information for the project. Magazines don't like to include pages of a PIC program since those require many pages of expensive paper (which needs advertising space sold to make it "cheap"). It isn't immediately flashy and the program writers don't always include Comments in source code sufficient to make the program flow clear at first reading.

Ready-built, off-the-shelf amateur radio equipment DOES use one or more microcontrollers internally. You cannot truly qualify that "most" hobby projects use them. :-)

>This isn't some comspiracy, they make the whole project
>simpler, less expensive, and more flexible.

Totally agreed. However, in fairness, use of a microcontroller in a ham project is NOT traditional analog circuitry (that some old-timers insist is the "only" kind of "radio"). It does NOT exemplify the mass of mechanical structures used in 3 and 4 decade old project pictures looked at many times in old handbooks...looked at in emotional awe and wonderment. Microcontrollers are NOT traditional components and have functions unrelated to physical mechanics that they often replace. Different. Minds have to adapt to NEW ways to do things.

>Granted, there is a learning curve if you've never done it before, but I
>would expect that someone who wasn't totally terrified could learn enough to
>make the sorts of changes he might need to an off the shelf project, build
>the programming hardware, and get the project working in less
>time/effort/money than simply getting a reasonable number of LED digits
>wired and driven!

Of course. :-) The pep-rally over-confidence syndrome...one can do anything with a "positive outlook"...immediately...no problems at all, right? :-)

In a remote way, yes. Unknowns are not a "terror" to everyone. They should be just things unknown that must be learned in order to apply them. That takes some skull sweat at becoming familiar and such study takes TIME. Such learning time seldom provides immediate solutions to a present project but it has incalculable worth in being able to apply the micro techniques to all sorts of future problems.

Why bash anyone for wanting to use LEDs instead of LCDs? There are advantages to each kind of display. For a personal project, I would think that it is up to the individual to determine individual desires. Is there something "wrong" with individualism? I think not.

I'm working on inventing anti-gravity...but something's holding the project down.

You are right Tom.

But my question was that when the sensitivity, for example 1 kohms/volt, is known, can one then also know, without further measurement, the internal resistance.

And from what I gather the answer to that question is NO.

thank you all

Uwe

>And from what I gather the answer to that question is NO.
>
>thank you all

In actual practice, d'Arsonval meters vary in internal resistance.
The "Ohms/Volt" rating is only approximate.

D'Arsonval meters consume DC power dependent on the meter
motor (the coil winding driving the needle) position. Miniscule power
to be sure but finite power demand. If the power of movement and
display is the criterion for "sensitivity," then the meter resistance
must be measured or known. That is imperative if the meter is to
be shunted for a higher actual current indication.

A millivoltmeter can measure the meter motor voltage drop at a
given current through it. Law of Resistance will then apply to find
meter motor resistance from current and voltage. To shunt a
meter for higher current the external shunt resistor must have a
value equal to the meter motor voltage drop divided by the total of
desired current minus the meter current. At high current full scales
the shunt resistance becomes quite low and the meter motor
resistance is negligible for accuracy of high current. At low current
full scales approaching that of a meter alone, the meter motor
resistance is an appreciable part of the shunt resistance.

In voltmeter applications, a series resistor is approximated by the
"Ohms per Volt" value on relatively high full-scale ranges. That series
resistor should be (for precision) the quantity total voltage drop minus
the meter motor voltage drop, all divided by the meter current.

Fortunately, the meter motor resistance is small and the voltage drop
is quite small compared to the total needed voltage drop. The difference
in voltmeter resistance values between approximate and precision
becomes less as the meter current becomes less for a given full scale.
Note: For full scale voltmeter readings of 100 V and up, the approximation
of "Ohms/Volt" is quite good...one needs the meter motor resistance for
an accurate voltmeter indication of 5 V and below to fit modern digital
logic rail voltages.

One can expect most d'Arsonval meters to exhibit about 50 mV motor
drop at full scale...but could be almost any value from 20 to 100 mV.

When a variable coil such as a TOKO is spec'd as 150 nH, I assume thats the max value with the slug fully inserted. How must range adjustment is there in these coils,i.e.what would the min value be with the type43 ferrite slug fully backed out ? Also I'm modifying this slug tuned coil from 680 microhenries down to 150 nh, so I believe that should be about four turns of a much larger wiresize than the really fine wire on there now. Any comments appreciated. Am building the 200 watt fet amplifier in this month's QEX. Having a very difficult time locating the low loss ceramic ATC SMT caps, need 19ea 100pf and 7ea 300 pf caps. Apparently Aerovox won't respond to anything other than a large order.

That's called "capture ratio". Better receivers have lower numbers -
smaller difference required to suppress unwanted station. They have numbers
like a VERY few dB.

To get this you need very flat IF within the passband - no ripples in
response.

A wideband limiter and wide and very linear discriminator.

The National "Criterion" series of tuners from 50 years ago were among the
first to attempt this. IIRC, there were HH Scott tuners like this as well.

All bets are off if you're trying to recover stereo.

Re: parameters governing the power rating and the frequency range of an SWR meter

I am reading the article which was sent to me as a response to my question about SWR meters and their construction. The article, a section of the test equipment chapter of the RSGB VHF/UHF Handbook, explains the construction of a reflectometer for 2m.

The main line pick up tube is selected to match the impedance of the antenna line whereas the impedance of the sampling line can be more arbitrary and just has to be matched up with the proper terminating resistor.

So much for impedance matching.

The article did not explain very much what the limitation of the device with regards to the power and the used frequency are.

Ok, the power seems to be limited by the power rating of the resistors terminating the sampling line.
But then what parameter(s) are reponsible for the frequency rating of the device.

I am asking because at a local hamfest I picked up reflectometer parts and now I wonder if I can change those to fit my needs (144MHz and low power).

regards Uwe

What is the best way to attach a hall effect sensor in a TO-92 package to 22 gauge solid wire? I've tried just laying the wire next to the to-92 lead and soldering them together, but I don't get much of a mechanical connection doing that. Is there some type of sleeve I should be using prior to the soldering?

Also, any suggestion on encapulating the device once the electrical connections are made?

> personal programming experience, only in the installation of the micro.

Yes, but it has become clear that the original poster had a rather specific
application that he is not going to be able to get off the shelf for a
reasonable price. He will need to take an existing design and alter it, or
roll his own.

> Yes and no. :-) That depends on the source of information for the

> are advantages to each kind of display. For a personal project, I
> would think that it is up to the individual to determine individual
> desires. Is there something "wrong" with individualism? I think not.

Certainly, I don't think there is anything wrong with using LEDs. But the
original poster was looking for something low current - not a real strong

suit for LEDs. He was looking for something simple. LEDs are a problem there, too, because of the drive circuitry. If he is going to count frequency, within a project that he can get done this year, he is going to use a microcontroller of some ilk. Building a frequency counter from discrete parts is a huge job. And then, he wants it small. Again, the whole discrete logic thing makes that nearly impossible for the hobbyist. To top is off, he wants low current. Yes, absolutely doable with LEDs but with a huge added cost in complexity, especially if you decide up front no micros.

Frequency counters used to cost thousands of dollars. Today they are orders of magnitude cheaper because they are orders of magnitude simpler. And they are orders of magnitude simpler because virtually all the circuitry is in the micro. I just took a quick look at my counter - under 20 parts. Go to LEDs and you probably triple that. But take out the micro and you are talking about hundreds of parts.

Perhaps I am downplaying the difficulty in learning how to apply micros, but you are certainly downplaying the difficulty of not applying them in this context.

It sounds like maybe you had some sort of anlog frequency display in mind, which I don't quite picture. Might be a cool thing, though.

Your transformer secondary does not produce enough
voltage. First, solve that problem. You need a hefty
transformer, at least 15 volts on the secondary at
the required amperage. Your DC voltage across the
filter cap will be about 1.4 times the secondary
voltage.

The 723 circuits are great - but you can get all you
need from a 3 terminal LM 317 and a couple of support
components - a simpler circuit than a 723. Add a full
wave rectifier, and a lot of capacitance - I used
50,000 uf. Then, for the regulator, use an LM317 in
collector wraparound with a hefty heatsink and 4 or
more power transistors, with emitter equalizing
resistors. That's what I did, years ago. 4 2N3055's
on a huge heatsink and an LM317 on its own heatsink.
I used 4 .1 ohm 10 watt emitter resistors. If you
figure 7 amps per transistor, the emitter resistors
would have to dissipate 7^2 *.1 or 4.9 watts.
Each 2N3055 is capable of ~115 watts when used with a
proper heatsink. At 18 volts, my rectifier/filter caps
yield about 25.2 volts DC. The wattage to be dissipated,
worst case, is (25.2 - 13.8) * 25 or 285 watts. I have
no ripple problems and pretty good regulation, no load to

full load at about 10 amps. I haven't used the supply with a rig that draws more than that, so I can't say how well it would regulate at 25 amps, but I think it would work well.

What is really nice is that you can use almost all the parts in the above in a regulator with a 723 if you decide to, and you're out only the cost of the LM317 and support components not mentioned above - a few resistors, caps and a diode - less than ~ 3 bucks.

An example of the "collector wraparound" technique can be seen on page 13 of the following url:
http://www.national.com/ds/LM/LM340.pdf
It's title is "High Current Voltage Regulator"
It shows only 1 pass transistor - to add more, place them in parallel with the one shown, with one equalizing resistor in series with the emitter of each transistor. You can substitute a 7812 regulator for the 317 if you want - just put 2 diodes in series with the ground leg of the 7812 to get about 13.4 V out.

I hope that this post is not off-topic because it refers to the history of electricity which is the basis of our hobby. The other day I came across an interesting site written and maintained by Dr. Eugenii Katz from the Hebrew University in Jerusalem, Israel. It contains biografies, work and results of all the scientists who have contributed to the development of the science of electricity, ane wre born in the last 300 years. The list has 234 names - from William Gilbert to Walter William Schockley. If you click on the name you get his biography with his portrait (if avalilable) and inventions.

The whope list is diveded into five parts:

- scientists born before 1751.
- scientists born 1751-1800,
- scientists born 1801-1850,
- scientist born 1851-1900,
- scientists born after 1901.

It is enough to go to the Google and type in one of the above subtitles, and then click on the same subtitle you get. I have printed down the whole site - more than 800 pages of interesting reading! A whole encyclopedia for free. It is very useful for students of electrotechnics, but also very enlightening for us hams. I was shocked to read that George Ohm was mocked by respectful scientists for his law, that Nikola Tesla was pennyless in his old age and that Edvin Armstrong - the inventor of superheterodyne and of frequency modulation commited a suicide exhaused be endless court procedures and failures trying to introduce his FM.

Since my last post was only partial, I am repeating it here:

I hope that this post is not off-topic because it refers to the history of electricity which is the basis of our hobby. The other day I came across an interesting site written and maintained by Dr. Eugenii Katz from the Hebrew University in Jerusalem, Israel. It contains biografies, work and results of all the scientists who have contributed to the development of the science of electricity, and were born in the last 300 years. The list has 234 names - from William Gilbert to Walter William Schockley. If you click on a name, you will get his biography with his portrait (if avalilable) and inventions.

The whole list is diveded into five parts:

- scientists born before 1751.
- scientists born 1751-1800,
- scientists born 1801-1850,
- scientist born 1851-1900,
- scientists born after 1901.

It is enough to go to the Google and type in one of the above subtitles, and then click on the same subtitle you get. I have printed down the whole site - more than 800 pages of interesting reading! A whole encyclopedia for free! It is very useful for students of electrotechnics, but also very enlightening for us hams. I was shocked to read that George Ohm was mocked by respectful scientists for his Law, that Nikola Tesla was pennyless in his old age and that Edwin Armstrong - the inventor of superheterodyne and of frequency modulation - commited a suicide, exhaused be endless court procedures and failures trying to introduce his FM.

Dr. Katz's URL is:
<http://www.geocities.com/bioelectrochemistry/index.htm>.
An excellent work in his free time. Thanks, dr. Katz!

I just got this HP 456A AC Current Probe and need some help to get it going. The 1977 HP catalog indicates that it could operate 400 hours on batteries, not very long for what's in it. The dead batteries that came with it are Mallory TR 236R at 8.1 volts and TR 234R at 5.4 volts, these are C size diameter. There are only two 2N5087 transistors, a diode, and a few resistors and capacitors in the circuit, what's the current draw? I am not sure that these are the correct batteries but would like to know if anyone out there can be confirm the batteries or has a schematic, manual or AC power supply. If I can't find an HP optional AC supply I think I'll build a little Zener stabilized supply after I get the voltages confimred.
tnx

I believe that you are asking about narrowing the I.F. bandwidth. If you use narrow filters, this is quite possible. Since FM stereo stations occupy a 150kHz bandwidth, you would be clipping the sidebands, resulting in lost information. If you are only receiving in mono, this wouldn't be an issue.

I believe that the new Philips chipsets use DSP techniques for demodulation.
I also believe that this scheme is used in the Cambridge Audio T-500 tuner.
I do have one of these tuners, and it is the worst sounding unit out of my
collection. If it wasn't for the fact that it had a nice dual conversion AM
section, I would get rid of it.

I would like to use this 2 line VFD in a VFO project ... can see it a lot better than LCD. The part # is US1625D03B and it is a 5 volt part. I have a 21 page manual from the Inet and am trying to drive it with a PIC. This device uses a clock and data line and accepts 8 bit serial transfer. Have had minimal success.... I can display several characters on line 1 but when I try to send a stream of characters it starts a crazy oscillation on the signal lines and the display goes bonkers. I suspect the problem is timing and/or control character sequence. I remember the terrible time we all had with LCD's till someone cracked the control sequence mystery. I would appreciate any information or code samples to get this dude working.

Thanks

Ted in Atlanta KD4EE

A PIC in a DIP is physically no different than any other DIP. Plug it
in or solder it in. No problem.

What matters is the programming inside that PIC (or any other brand
microcontroller). That program's development is done outside the
DIP, then loaded into it. THAT is where the difference is.

It is more like a microprocessor (a microcontroller IS a microprocessor
plus some other circuits and functions) but the PIC is designed with a
small number of instructions. Far easier to memorize than the full
set for an Intel micro in a PC. Note: The memorization DOES occur
when starting to program or flow-charting someone else's program,
helps a great deal in reducing constant look-up to the instruction chart.

>> One MUST become familiar with "Assembler level" programming, of
>> including every single sequential command and decision point needed
>> by the program application.
>
>And this is different from designing with discrete logic how?

Do you want the whole book on that or just a synopsis? :-)

Hard-wired digital logic doesn't quite have "decision diamonds" but
some are close to that. I've programmed several micros, beginning
with an HP 9100 calculator, going on to Motorola 6800s, then to
MOSTEK 6502s (in the Apple][), Intel 8051s, the Intel family in the
PCs (through MASM), and finally the PIC 16Fs which I've just started
in on. The 6502 had a nice flag in the Carry of the accumulator that
Apple's DOS 3.3 made extensive use of...but there isn't an
equivalent discrete digital logic equivalent for that function ability.

Digital logic is fairly straightforward in design and application where
the main constraints are t_pd and fan-out/fan-in. Go for the states
and everything happens, no "program development" needed. One
CAN flow-chart some of it, or analyze states (especially so for a
state machine with a PLD) but most of it goes down on paper, can be
analyzed right off and applied. No program development needed.

>> The most convenient was to apply a microprocessor or micro-

So? The original request was - specifically - NOT to use an LCD.

>> Yes and no. :-) That depends on the source of information for the
>> project. Magazines don't like to include pages of a PIC program since
>
>No, but they always provide links to the code online. Have you opened a
>copy of QST lately?

Not since about two weeks ago. Just glancing through it. :-)

Have you "opened a Dr. Dobbs" recently? Or the PIC website to get
appnotes? [very slow for some reason compared to other sites] How
about a couple dozen websites with some ingenious applications,
including frequency counter applications not mentioned in here? Have
you opened a digital logic databook recently?

I've been source coding since the 70s and cannot immediately glean
meaning from a large listing of machine instructions. I don't know of
any professional programmer who can do that with unfamiliar source.

>> Of course. :-) The pep-rally over-confidence syndrome...one can do

>
>Certainly, I don't think there is anything wrong with using LEDs. But the
>original poster was looking for something low current - not a real strong
>suit for LEDs. He was looking for something simple.

No. He was looking for a display NOT an LCD.

As I said in my reply, LEDs draw far more current than LCDs,
and that will include large LCD display assemblies with their internal
local memory and screen driver circuitry.

>LEDs are a problem there, too, because of the drive circuitry.

Nonsense. A CD4511 is still off the shelf, BCD to 7-segment, latch
and decoder-driver. Just add series resistors for segments and play.
A buck apiece in single quantities. No programming.

>If he is going to count
>frequency, within a project that he can get done this year, he is going to
>use a microcontroller of some ilk. Building a frequency counter from
>discrete parts is a huge job.

From discrete transistors, yes. :-) From off-the-shelf ICs, no.
I did all the design and building of my own "discrete" frequency
counter and time interval meter using RTL back in 1967...while busy
working at a place with a long commute. I'm glad RTL got
discontinued. :-)

Since then I've done a small CMOS (4-digit) counter and am finishing
a "discrete" 74F and 74LS (TTL) 7-digit counter with adjustable preset
capability and up-down counting (!!).. Step-and-repeat for all those
digits. LED display. Why? I wanted specifically a display I could see
out of the corner of my eye (therefore bright) while concentrating on
work right in front of me. It is a workshop instrument, not a QRP thing
to take up a mountain. If I wanted such I would bring up the PIC
developement program, sketch flow charts, write source code (with
lots and lots of comments to tell me what I was doing in the future)...
and add more very-portable-rig functions and use a small LCD display
to save on battery drain.

>And then, he wants it small. Again, the
>whole discrete logic thing makes that nearly impossible for the hobbyist.

Why are you emphasizing all that "discrete logic" thing? Extremely
easy to use that from low-cost off-the-shelf items if one is familiar with
the available logic packages. Legacy parts. Old, some have already
been dropped from production.

>To top is off, he wants low current. Yes, absolutely doable with LEDs but
>with a huge added cost in complexity, especially if you decide up front no
>micros.

No. Using LEDs is NOT "low current." Not even for the first scientific
calculator. The HP-35 may have approached a practical limit on
LED numerics at _minimum_ current but it doesn't compare with LCDs
except maybe those LCDs with bright backlighting.

Who was mandating "no micros?" Not me. The scheme to use an
internal counting register as an initial accumulator is fairly recent (about
within the last 6 years). "Discrete" logic (very discrete, including two-

transistor flip-flops) counters go back to before 1960.

>Frequency counters used to cost thousands of dollars.

My 6-digit RTL counter, using all-new parts off-the-shelf, cost less than $300 in 1967. Included many extra parts, some still in the workshop parts collection, unused. Had oven-controlled 10 MHz timebase crystal. Today my timebase standard is a TCXO which will become a TCVXO when the 60 KHz phase-locker receiver-controller is completed. The display is LED only because that is _easy_ to implement, a no-strain thing and it is bright. Yes, brightness takes current but this is a lab instrument and not battery powered. The total parts cost is less than $500 for both halves in 2003. Absolutely NO programming required.

Yes, I do know the cost of manufactured instruments. Was calibrating HP 524 counters in 1960 (B model was all vacuum state, maximum count frequency of 10 MHz, neon "thermometer" numeric display, weight excellent for body building).

>Today they are orders
>of magnitude cheaper because they are orders of magnitude simpler. And they
>are orders of magnitude simpler because virtually all the circuitry is in
>the micro. I just took a quick look at my counter - under 20 parts. Go to
>LEDs and you probably triple that. But take out the micro and you are
>talking about hundreds of parts.

A 16F84 or 16F71 as a frequency counter needs only a Schmitt trigger input to shape up the arbitrary waveform, maybe a "discrete" comparator IC if one is fussy, to count directly to 30 MHz. Going higher in frequency needs an extra "discrete" IC, a prescaler. That and an LCD assembly, one of many kinds available.

The stuff NOT in "discrete hardware" is the PROGRAM. Do that one right and it is a fine little instrument. Do it wrong and there is a struggle to right it that may take hours and days, including bench measurement. Using others' source code is fine, much much easier. Provided the LCD assembly is the same as the authors', but if you have an LCD with a different sequence of data, of format, then it is back to the development program again.

>Perhaps I am downplaying the difficulty in learning how to apply micros, but
>you are certainly downplaying the difficulty of not applying them in this
>context.

I thought I gave a reasonable reply the first time. Looked at several options. Were you gathering sticks for an Internet burning at the stake? :-) When giving suggestions it is better to cover the wide range of possibilities first rather than second-guess another's depth of knowledge, experience, or desire.

>It sounds like maybe you had some sort of anlog frequency display in mind,
>which I don't quite picture. Might be a cool thing, though.

I've been using displays of many kinds in a long time, starting with gas numerics (Amperex Bi-Quinary tubes, like a Burroughs Nixie but 2 x 5, not 1 x 10)...and going through all the others except plasma dot matrix panels. If it's an LCD and there's a circuit driver IC for it, I will use those first. The weird waveforms have already been worked out and the ICs packaged. No driver IC and I start looking at other ways to display information. I don't know everything but I've been around a while and had hands-on in many things.

When you say "discrete" active devices, try to put that in context of individual transistors. Or tubes. I've done both. Never again, I hope. You ought to call TTL and functional-equivalent CMOS logic as either SSI, MSI, or LSI (which they are) not "discrete." Done those in more than counter circuitry. Microprocessors and microcontrollers fall under the VLSI category.

Microcontrollers are wonderful devices for making certain things with very low hardware count and near-minimal power demand. But, their application in special things requires PROGRAMMING. That isn't in the hardware. Such MUST be there. It CAN be learned. Some, like me, find programming fun. Others do not. I do not find having to learn new instruction sets for other micro families to be fun. Nuisance.

Was there anything else? :-)

>mechanical connection doing that.

Good soldering technique forms a very strong intermetallic bond
by itself. Tektronix proved that in production of their first
oscilloscopes, just laying in wires to terminal posts instead of
wrapping them first.

>Is there some type of sleeve I should be using prior to the soldering?

Teflon prior to soldering. PVC sleeve after soldering. Either.
Your choice.

I would suggest #24 or #26 gauge wire, maybe a tweezer-like
heat sink to avoid too much heat into the TO-92 plastic case
through the leads.

>Also, any suggestion on encapulating the device once the electrical
>connections are made?

Any two-part epoxy having a filler...making it "thick" or viscous.
That will bond nicely to the epoxy TO-92 case.

I've made a temperature probe out of a 2N3877 in a TO-92 many
years ago using #24 stranded. Leads soldered in-line with the
transistor leads. Thick epoxy over the leads. Diameter was no
larger than the TO-92 largest diameter. PVC sleeving slipped over
the soldered joints after soldering...I think...epoxy covered it up. :-)

The only problem was the overall mass of the probe as a
temperature measuring device...got replaced with a welded
thermocouple about a decade after fabrication in 1968. Still works
for temping large masses. Hall effect is for magnetic fields and the
method is non-magnetic unless there is a strange epoxy with a
metal powder filler.

Hank,

According to my 1967 HP catalog (in surprisingly good condtion, by the way) the 456A uses two TR233R's and one TR234. It does not list current required (and I guess the 1977 catalog does'nt either.)

My catalog also estimates battery life at 400 hours.

You might search the net for mercury battery current capacity. I seem to recall it is somewhat less than nicads, but I don't remember the ratios.

73,

Phil - N4GWV

1308. Tektronix 2235 Intensity control Problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-16 00:16:11 UTC
From: "John B"
Message-ID: <fZTXb.5518$aH3.176217@bgtnsc04-news.ops.worldnet.att.net>
Source record: 28595

Recently purchased a Tek 2235 (does not have military option). It displays both traces ok as well as a square wave on both channels. Both traces respond to the 'A' intensity control, while the 'B' intensity control has no effect. Has anyone else experienced this problem? Both the 'A' & 'B' intensity control pots check out ok. Voltage at the base of Q814 varies when the 'B' pot is turned as well as the output voltage on the emitter of Q814. Voltages here are correct too. There is no voltage change at the node of anodes CR818 and CR820 while turning the 'B' pot, but it does change here when the 'A' intensity pot is turned. I've checked all related diodes --CR818, CR820, CR805, CR817, CR816, CR680, etc., and related resistors. Q586 is biased and stays on in "Ch1", "CH2", and "Both" positions, at least as far as I can tell with the voltmeter. I don't see any components with visible damage, but there is a place on the board that is brown from heat around Q254, Q255, Q256 which is the Vertical output to CRT section. I'm guessing that this is unrelated to the intensity problem. any help or ideas would be greatly appreciated.

Thanks,
John

I think it boils down to something very practical:

If you want good spectral purity, then you need to bandpass filter the output of the multiplier. It becomes a matter of how close and how large the undesired spectral components are compared to the desired spectral components. After that, you can consult your filter design charts to determine how complex a filter will be required and whether it's physically realizable.

As an example, a x4 multiplier stage will have a desired output at Fin x 4, and close-in undesired products at Fin x 3 and Fin x 5. This means the output bandpass filter has to be able to attenuate signals at +/-25% of the center frequency sufficiently to meet the desired spectral purity. In practice with simple single-ended multiplier designs, a x4 multiplier is approaching the threshold of realizability for high purity applications (40-60 dB purity). It is possible to make push-pull and push-push multipliers that have better output purity, but these techniques are seldom used.

1310. How do you use an LCC SMD device - holders or carriers or ??

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-16 01:05:07 UTC
From: rmonagha@engr.smu.edu

Source record: 28497

Greetings,

I would like to use a ceramic 8 lead LCC device (accelerometer) in a project but wonder on the best way to mount and use it in a one-off project? The device is 5x5mm square, three contacts on each side and one contact on top and one on the bottom (total 8). So we are dealing with 1mm spacing - eeek! ;-)

Are there snap in holders which can be used to mount these devices and prototype with them, sort of like chip sockets for 14 pin DIPs, with wire fanout to pads for soldering or connections?

I have searched online, but the closest I have found is the surfboard series for surface mount devices (digikey etc.). This still leaves the issue of soldering in such close and tiny spaces. Given $20+ per device, I would like to find something which would allow direct snap in mounting.

Is there such a device available? Who stocks and sells them?

Thanks very much for your help in this project!

regards

bob monaghan W5VC

I would think a "W3JDR" would know that even harmonics are *much*
harder to obtain in nonlinear multipliers.

John:

Are you triggering the B sweep before checking out the B intensity control?
The B intensity controls only the delayed B sweep, not the main (A) sweep.
You may know this already and have other hardware problems, but set the B
trigger
to the 'runs after delay' position, then decouple the A and B sweep knobs.
The
delayed sweep will be offset from the main sweep (you can see 4 traces),
and the B intensity should control just the delayed sweep. Usually the
delayed
sweep is a lot fainter than the main sweep because it's effective trigger
rate is low
compared to the sweep rate.

Right! I got one for $5.00 - a Ramsey with a cold
solder joint, works perfectly now, and another
for $10 - goes only to 50 MHz, both at hamfests.

Thanks Tom. you were right, the B sweep wasn't triggered. I'm not used to this model, and (as you can probably tell) it's been a number of years since I have even used a scope. Nothing is more frustrating than to chase a problem that doesn't even exist. :-)

73's,

John

While you might be able to generate odd harmonics of a 1 kHz square wave up to several hundred megahertz, there are two practical problems.

First you would need some method to separate the wanted harmonic from the unwanted.

For low multiplication factors in HF/VHF a series of bandpass LC filters would be needed to attenuate the unwanted harmonics. For higher frequencies some helical or cavity resonators may be needed.

One old method to separate nearby harmonics is to use a wave analyser. The wanted harmonics is mixed down with a VFO to some fixed intermediate frequency in which a fixed crystal filter is inserted (bandwidth 0,5-50 kHz depending on application). The filtered and amplified signal is then mixed back to the original frequency by the same VFO. The absolute stability of the VFO does not matter very much, since any drift is cancelled in the up-conversion. However, the stability must be sufficient to keep the desired harmonics within the IF filter bandwidth. This kind of tricks was once used to multiply some high precision frequency standard to some odd (say 61th harmonic).

The other problem with high multiplication factors is that the amplitude of the higher harmonics is quite low, thus needing quite a lot of amplification after filtering. However, the level of the original harmonics was low compared also to the wide band thermal (white) noise, thus, after amplification, the wide band thermal noise level is also high, reducing the final signal to noise ratio and in reception, cause reciprocal mixing programs.

Thus, it is better to use several multiplier stages with low multiplication factors, since it easier to filter out the desired harmonics after each multiplier. The gain distribution is also better, thus the noise floor does not become uncomfortably close to the wanted signal.

However, if some strange multiplication factor (such as the 17th) is needed (in which case a series of multipliers can not be used), these

days it would be easier to use a PLL with a fixed digital divider. Keep the VCO tuning range as small as possible, thus reducing the MHz/V sensitivity and noise through the tuning line and use a large loop bandwidth to clean the areas around the generated signal.

Is that the ADXL202? I made a little PCB for it, similar to the one used
for the evaluation kit. Soldering the device was a bit tricky (I should
have used solder paste) but I managed it with a fine tip and a
magnifier. You are very unlikely to find a socket for it, it just isn't
suitable for one.

I suppose it boils down to how much signal is left in the mush as the
harmonics get higher and higher. Knew I shoulda held on to that
spectrum analyser I used to have. :-(
I suppose that's the proper answer though: get the rise/fall times as
small and possible, measure the specral output and pick a suitable
harmonic with enough energy in it to set it 'comfortably' above the
noise floor?

I don't have the pinout, but it should be easy to figure out with an ohmmeter. Between two of the pins, measurements will show a diode. The anode of this diode is the source, the cathode is the drain. The remaining pin, which will measure open circuit in either direction to the other two, is the gate.

I guessed I missed Jim's comment in the earlier post, or I would have replied earlier. Jim, I'm not not sure what you're trying to say, but there seems to be a sarcastic undertone to the way you said it.

Anyway, it turns out that non-linear single-ended elements are great generators of even-order harmonics. That's why the classical HF/VHF multiplier circuit is typically a single ended transistor amplifier with output and input tuned to different frequencies. If you bias the device so it is non-linear, then it becomes a natural harmonic generator. You can enhance even-order generation and supress the odd-order generation by using a non-linear 'push-push' stage, just as you can suppress even order harmonics with a 'push-pull' stage.

In either case, the important thing to remember is that symmetrical clipping or limiting generates mostly odd-order distortion and unsymmetrical clipping or limiting generates mostly even order distortion. The quantification of this is left to those more mathematically inclined.

Thanks to David DiGiacomo I've got the info and it looks like the B+ is 5.4 VDC at 5.5 ma and the B- is 8.1 VDC at 20 microamps! HP used a small centrer tapped transformer at about 25 volts that was regultaed down to the 8.1 and 5.4. I can't find anything on the physical size of the xfrmr but it has to be no bigger than end of ones thumb,but maybe they used a wall wart but I kind of doubt it. I've not had any experience with real small low current xfmrs that take 115VAC to 20 or 30 VAC and would appreciated any ideas on what to use. A wall wart would be my last resort.

It depends on what your are starting from. If it's a sine wave, yes
even harmonics can be made from diode non-linearities.

The OP has a inverter-style XTAL oscillator, output very nearly
square.

A square wave is rich in odd harmonics, a perfect square wave has NO
even harmonics.

I didn't have any luck bidding on EBAY.

So I just built a PIC 16f84 based 4 LED digit counter. In less than a week I built the programmer, learnt to use the MPASM, breadboarded the demo circuit and found a lot of PIC based counter projects. I'm learning to code slowly but at least there are only 35 instructions.

The LED's take up to 10mA per digit.

I found most popular LCD modules have a standard Hitachi HD44780 interface

1330. Damping Higher Harmonics on a parallel LC-Oscillator? (1 port Low-, High-, Bandpasses?)

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-16 18:35:27 UTC
From: abcdstutzer@evard.ch
Message-ID: <aca3ec4c.0402161035.12f1d8ac@posting.google.com>
Source record: 28517

Hi,

I built a small FM Radio as shown on
http://members.aol.com/torkraemer/ukwsender/ukwsender.html.
As it is it works pretty well, allthough I operate it without any
adition antenna.

Of course there are pretty high (unwanted) peaks in the frequency-band
at multiples of the operating frequency.
Because I don't want to use an additional antenna, I can't filter the
signal on its way from L1 to the antenna with a common "2-port
Bandpass".
Putting such a Bandpass (or Lowpass) between the DC-Source and the
LC-Circuit did not seem to work well.

So how can I damp those harmonics on L1 Coil? I thought of some kind
of frequency dependent impedance in parallel with the Coil.

I tried this with another LC-prallel Circuit which has an impedance of
approx. 0 Ohms at 200 Mhz. This works as expected but seems a bit
unsophisticated and the Impedance falls too slow as the frequency
approaches the 200Mhz.

Unfortunately I have no Idea how to design a "higher order
1-port-Bandpass", or even more likeably a Highpass.

What would you recommend?
What shoud I read?
Any suggestions are welcome.

Thanks to all, and sorry for the lenght of the message.

Diego S.

Not really, Jim...unless you mean something special by "nonlinear multipliers" like diodes/varactors which I suspect fall under your comment. In the two-way radios of the 60's & early 80's before synthesizers, I designed many a single stage multiplier of 2x or 3x, which were preferred and sometimes 4x. They worked very well...using cap input coupling, to keep the base Z low at the harmonics and keeping the conduction angle optimized for output level. Also, the adjacent harmonics are easier to filter than higher orders of multiplication (when that is a factor. Only a single resonant circuit was required between stages.
The bottom line depends upon the spurious requirements. Then there are always preferences for what we may have used in the past - and what the application actually is.
Starting with a spectral comb(like a square wave or other pulse-type waveform) and picking off the desired harmonic can also be very effective, but again, it depends upon the specific application.
I did a synthesizer mixer with no tuned circuits to get from 40 MHz crystal oscillator to 220MHz to mix down a VCO to an IF for the programmable divider. Was really sweet! Did the same for what I believe was the very first synthesized 2M hand held in 1973. A Motorola HT220. Even had the Transmit VCO _ON_ yes _ON_ the TX frequency. Total current drain was 7ma. Tx spurious (-70dBc) better than the original (-35-40dB) Still have it.

Starting with a perfect square wave at f1, bang the hell out of a diode
with it, and then bandpass it and the 3rd harmonic (f2) separately, then
mix them to get f1, f2, f1+f2, and f1-f2. Using a doubly balanced mixer
will get rid of f1 and f2, then notching out f1+f2 will leave f1-f2,
which will be 2f1, that non-existent second harmonic.

I believe he is talking about adjacent channel signals which are much
stronger than the desired and trying to see if there is a way to "fix" that.
Capture does not apply for this situation. Capture is a co-channel effect
and is better the wider the whole system is, not just the IF.

Oh yuchh...that sounds painful!
Why not just distort the symmetry of the square digitally (like drive it into an exclusive-or with a small delay on one input) to make a short impulse, then bandpass filter the output? Or staying in the purely digital domain, use same said exclusive-or and delay one of the two inputs by t/4 (t=period of input sq wave) and get a 2*F square wave out.

Paul, past state of the hardware art (past 60 years) indicates that triplers are the practical maximum. Quintuplers have been done but those are rare in described applications.

In 1955 I had hands-on experience with a septupler (7 x multiplier) using a 2C39 and a cavity-tuned plate circuit at 1.8 GHz. That was in a General Electric microwave radio relay terminal designed about 1950. Of nine terminals, two had to "QSY" to new crystal-controlled microwave center frequencies for second-level contingency operation. Difficult and fussy to do but was do-able...the crystal was also 7th overtone in a vacuum tube oscillator but was followed by a buffer stage feeding a tripler, another buffer, then the septupler which fed another 2C39 as the pulse-modulated final for 12 W peak output at 1.8 GHz. [from memory and 35mm slides...big GE manual went to recycle a long time ago] That's the only septupler application that I am aware of...no doubt there are others, somewhere.

General Electric must have had some division/work-group with lots of work in old frequency control methods. A local NTSC color sub-carrier generator-regenerator made by GE had extensive use of "locked oscillators" for frequency multiplication and division, but mostly at frequencies lower than 7 MHz. Haven't come across any practical hardware on locked oscillators except for two mentions in older journals, trade papers. One of those used transistors as active devices.

Doublers and quadruplers have been made using both diodes and tube-or-transistor active devices. That's relatively easy with non-square waveforms (distorted sinewaves); square waves have high odd harmonic energy, low even harmonic energy.

Making practical, reproducible active multipliers in the home shop is, practically, a trial-and-error process involving playing with cut-off bias of the active device input, energy and harmonic content of the source, and Q of the multiplier's output stage. In the past I've made tripling-in-the-plate pentode crystal oscillators using fundamental frequency quartz but those were highly dependent on getting the highest impedance tuned plate circuit and needed scope viewing to check output waveforms. Not very reproducible.

There's no "easy" way to do it that will "work every time" despite
the claims of many. :-)

Digital division IS straightforward up to about 1 GHz based on
such technology over the last 3 decades. That's why PLLs came
to prominence in frequency control techniques up to UHF.

...or just use a small toroid transformer, a pair of diodes arranged
like a full-wave rectifier for wideband frequency doubling? :-)

While using digitial techniques sounds cool at first, the above
technique can generate all kinds of PM that isn't noticed on time-
domain viewing with a scope. There are many ways to cure that PM
or incidental FM but all involve lots more circuitry than the simple
diode doubler which can be inherently broadband over half an octave.

Depends on the application of the multiplier and the overall specs
on purity of the multiplied RF.

Capture effect:

http://en.wikipedia.org/wiki/Capture_effect

It's an intersting phenomena, and potentially useful. If I could phase null (at the antenna) the local stronger signal then it would dissappear as inteference if it was a few db below the wanted signal.

Only problem is, is that if you cannot get the inteferring signal below the wanted one, it's works very bad for you, because you cannot listen to an inteferred with signal. Which is better than nothing I guess in some cases.

Pity that somehow you cannot design circuitry which recognises a 100Khz difference between the wanted FM station and the unwanted FM station and proceed to demodulate the wanted one only. If it were possible, it would have been done by now. Maybe you could do it digitally,I dunno.

What purpose does the diode serve? You're already starting with a
"perfect" square wave.

OTOH, if you have had some bad experiences with diodes in the past, I
can easily understand your tendency to abuse them as often as you can.

Jim

No need to abuse any diodes. The third harmonic is already there, just
10 dB down. You only need a bit of gain after the peaky filter.

Here are some links to related projects involving PIC micros:

http://lea.hamradio.si/~s57nan/ham_radio/fmtr.html

http://www.qsl.net/om3cph/counter/ldc/contribs/pic_flck.htm
- includes an interesting "huff and puff" variant for VFO locking

http://www.qsl.net/g6uyj/freqcounter.html

http://members.optushome.com/vk3biz/micro.html
- basically a page of links to microcontroller projects

The first three are quite detailed in their descriptions, include source
code and pictures of completed units (two have PCB patterns).

Two pages of hits using search string "PIC frequency counter." There
are more sites of project examples out there.

But I believe not here. Only for co-channel interference.

> If I could phase null
> (at the antenna) the local stronger signal ... if you cannot get the
> inteferring signal below the

This is a sticky problem if the undesired is only 100kHz off center with the standard 200kHz system design. I this case you can have significant energy within the Rx passband coming from the undesired. I can't say how low the undesired needs to be.

>

As you have surmised, the "null in the antenna pattern" is probably your best bet. This is done in some rather dificult situations. One is on a radio equiped copter where the undesides TX is on board! (the TX output itself can be sampled) The antenna with a null would be my first path. I also have an FM band adjacent channel problem I'd like to solve and will (when I get time) try a nulling antenn.

The "adcock" type would be one of the easiest. Two vertical dipoles (probably folded, but not necessary) fed out of phase. There are two nuls toward the "flat side" or broad-side. Point the null at the undesired. The "two vertical cardioid" is just as easy. I think it is two vertical dipoles spaced (I think) 1/4 wave apart with a 3/4 wave coax (electrical) between and fed at one of the dipoles. The 1/4 wave (free-space) physical s pacing gives 90 degrees and the 3/4 (in coax) gives another 90 for a total of 180 - thus cancelling. 3/4 coax is needed because 1/4 will be shorter that the free-space 1/4 spacing of the dipoles.

I recently saw both of these in the Ham transmitter hunting book. They are probably both on the net if you know where to look. Try amateur radio DF or

ARDF.
http://members.aol.com/BmgEngInc/Adcock.html
Probably the transformer is not needed.

I took a quick look and can't find more, so Here's a web ring on DF:
http://m.webring.com/hub?ring=foxhunt

Other DF sites, but I don't know if they have for U. Some have more links.
http://www.panix.com/clay/ham/rdf.html
http://www.ardf-uk.co.uk/index2.html
http://members.aol.com/fdecker/rdf.htm
http://members.aol.com/homingin/index.html
Dual null & cardioid figures, prpbably not helpful.
http://members.aol.com/homingin/hfinderfix.html
Lota' links
http://members.aol.com/homingin/links.html

Another technique would also handle the afore mentined multipath problem.
This I will call the "Secondary Antenna & Canceller" (SAC) technique. It is
used in the military and commercial arena to solve some sticky strong signal
problems.
A secondary antenna is used and fed to an amplifier which has phase and
amplitute adjustments (under computer control for automatic tuning). The
output of this is fed back into the RX line (where the desired and undesired
signal are) and tuned for minimum interference. This amounts to a custom
antenna null. MFJ makes two for HF

Not radio, but interesting nevertheless. The older Hewlett-Packard cesium clocks, ie 5060/61/62 vintage multiplied a crystal oscillator up to 90 MHz in several stages. This fed into a step-recovery diode that sits in a cavity, and has 12.631... MHz applied to the SRD bias. The cavity selects the ***102nd*** harmonic ie 9180 MHz, and there are also sidebands at +/- 12.631.. MHz This is then fed into a hi-Q cavity tuned to the upper sideband ie 9192.631... MHz which is the desired cesium transition frequency.

Adjusting the whole thing was a bit fiddly, and there were also some factory-set adjustments that you NEVER TOUCHED unless you had plenty of time and a squillion dollars worth of test gear. This was all a 1960's design and was a bit of a stretch. The newer (5071) clocks do things QUITE differently.

An idea:
Use shunt feed and a pi network. It is a low pass filter. Since TR1 is
also the oscillator, you may need to add an amplifier.

```
+V
Choke
|
|-------Coil----> ANT
| | |
| = =

Simplistic explanations of "capture effect" don't help here.

The main, major cause of such strong signal interference is due to
the FM receiver's LIMITER stage. That stage (usually there are 2 to
3 of them) is biased such that a strong signal is going to clip or that
it will actually develop enough self-bias to clip even further. The end
result is that a limiter output is primarily composed of the strongest
signal's RF energy.

The action of a limiter is basically that of accepting only the strongest
signal and "pushing down" the energy of weaker signals, including
noise at the noise floor of the front end. THAT is what insures the FM
"clean signal" quality. It is also a sort of automatic AGC so that all
signals of the same modulation index will be demodulated to the same
audio level...even though the antenna input signal can vary considerably.

Such limiters have been used for some pulsed RF reception with the
ability to "push down" offending pulsed carrier frequencies' envelopes.

>Pity that somehow you cannot design circuitry which recognises a 100Khz
>difference between the wanted FM station and the unwanted FM station and
>proceed to demodulate the wanted one only. If it were possible, it would
>have been done by now. Maybe you could do it digitally,I dunno.

Not with "phasing" alone and not with limiters still in the IF chain. But, it has been done by other means -

The brute force method is to use a many-pole crystal bandpass filter ahead of all limiters. Even Heathkit did that. This cuts out very strong adjacent signals and the limiters will be less affected by such. With steep skirt selectivity, offending adjacent channel attenuation can be 60 db or greater.

A second method is to discard the limiter stages and try for a Ratio detector instead of the Foster-Seeley discriminator variants plus AGC on the non-limiting IF stages. Not a perfect solution but does work to some extent. Most NTSC TV receivers use a variation of that for TV sound, originally started many years ago as the "intercarrier sound" system to replace a separate limiter-discriminator IF strip; the first TV receivers actually had TWO IF strips...:-)

The most obvious way, and least familiar, is to use a large-bit digital A-to-D system and high-speed microprocessor to (1) Do the channel bandpass filtering with a "brick-wall" filter routine; (2) Do the FM demodulation directly after digital bandpass filtering by summing the sideband components of the FM signal; (3) Converting the demodulated IF in digital form back to analog audio. That's been done but the production costs for consumer electronics systems has only lately come down enough to warrant such use.

All of the methods I've given are prior art.

In the UK, where I am, the spacing between channels is 100Khz. And that is a real problem, because, as you say a lot of RF energy from the undesired station gets into the IF passband.

And so basically I was wondeting if the technolgy exists for the RX to know that energy from the undesired station, 100Khz off frequency, is to be ignored in the demodulation. I don't think it can be done, but if it could somehow the electronics would have to associate the unwanted energy with a non wanted station, and in a sense, ignore it. Just wondering if the technoloy is around to do that. Probably not. Only likely possible thru digital computing methods maybe.

looking at the leaves, "depth of thread" in inches seems the most
plausible to me. This item would date back to the 50's, I don't
believe there was too much metric action in American machine shops at
that time.
~~~~~~~~~~~~~~~~~~~

I'd try _measuring_ the depths with a micrometer, but I don't know where to measure to/from. How is thread depth defined? And by the way, who sets the standards on how these things are measured?

1354. thanks! Re: How do you use an LCC SMD device - holders??

Thanks for the tips - glad to hear that it has worked for others ;-)
I have read up on the SMD use tips on several homebrew sites, but I'm not
sure my hands or eyes are good enough to do this. I'm just amazed there
aren't some snap in setups, esp. given the cost of some of these devices.

regards and best wishes to all

Hi, guys,

ISTR.......
(through the mists of time) that the excessive bandwidth of an AM
transmission signal can interfere with the reception of a NBFM signal,
though the converse is not true. Can anyone confirm this (or else
flatly deny it/affirm it)?

Thanks,

p.

I don't think you can make a flat statement either way with the information supplied. The only thing that's for sure is NBFM has a constant power envelope whereas AM has a highly variable envelope. And why do you say AM has excessive bandwidth?. NBFM only can only approaches the bandwidth efficiency of AM when the FM modulation index gets very small.
When FM gets narrow enough (expressed by modulation index, not deviation), it's interference rejection is no better than AM.

Yes, the 026 had the round keys but the 029 keyboard was basically the same
as the 129 (e.g., square keys).

Not a lot of difference otherwise between 029 and 129 keyboard, although
IIRC the 129 had a pair of LED 7-segment displays (fairly small in size)
which showed the column number [since the machine didn't have a drum card
assembly like the 029 did with the rotating numbered "scale" and fixed
pointer underneath it]. Also, the 129 had a big (relatively speaking)
rotary switch w/plastic knob on the area above the keys themselves to select
which program was currently active.

>flatly deny it/affirm it)?

Paul, you need to be a bit more specific on the above.

First, if the AM carrier is not close to the FM center frequency, then
the only energy from the AM signal is from the sideband content of
the AM.

Second, if the AM sideband energy is below the FM carrier level,
the FM receiver limiter is going to do its suppression thing and
(in the receiver) lower the AM sideband level. The amount of AM
suppression depends on the relative no-modulation signal levels of
the two.

Alternate second: If the AM signal, any part, is stronger than the
FM signal's level, then the AM signal is going to "take over" and
that limiter will suppress the FM signal.

If the FM signal's swing happens to intrude on the passband of the
AM receiver - and its level is high enough - then some distorted
modulation from the FM signal will come through. The higher the
relative FM signal is to the AM level, the worse the interference from
distorted FM content. Conversely, if the AM signal is stronger than
the FM, then the distorted interference from the FM signal is less.

Very basic RFI stuff. You can confirm this yourself with a receiver
capable of demodulating AM and FM (make it narrowband if you
want, doesn't matter much here) and reasonably-calibrated AM
and FM signal sources. The interference of one against the other
will be due almost entirely to relative signal levels and the carrier
(no modulation) frequency differences versus the receiver selectivity
bandwidth.

About the only thing different between FM and NBFM in the receiver
is the final selectivity bandwidth. There will be some sort of limiting
in there even with simple detector types.

^^^^^^^^^^^^^

If you multiply the two numbers together, you get about 0.12 for every pair, so they are reciprocals multiplied by the constant .12. That means that the numbers are related to the distance per thread, or the thread depth in some way, but I havn't taken the time to look for it.

Hi
First are you driving the Futaba with the SSP Serial Synchronous Port
found on most PICS? These work better than just posting data on any
I/O line and clocking it on another. From looking at the spec's, I do
not believe speed is the problem but synchronization of data and
clock. Personally I like to use parallel interfacing because you have
greater control over the data. Of course that would require more data
lines.

While the sidebands above the wanted nominal carrier are mixed with
the lower sidebands of the unwanted signal, but if the lower sidebands
of the wanted signal and the upper sidebands of the unwanted signal
are free from any interference, it might be possible to determine
which sideband belongs to which signal and then demodulate them
separately.

This would at least require that all IF sidebands of both the wanted
and unwanted sidebands are digitised (prior to the limiter) and then
do some frequency domain processing after FFT.

When looking at an ordinary FM signal in frequency domain, there are
an infinite number of sidebands on each side of the nominal carrier
frequency (while in AM there is exactly one pair of sidebands) at
integer multiples of the baseband (audio) frequency. However, the
amplitude for each sideband is determined by the Bessel function of
the modulation index of each baseband signal. While the modulation
index for most audio tones is in practice quite low (below 5), there
are only going to be a few sidebands with any significant amplitude
around the nominal carrier. Thus, the bandwidth of an FM signal is not
infinite in practice.

For instance, in a stereo transmission, there are quite a lot of
signal amplitude around the baseband 38 kHz subcarrier frequency in
the area 36-40 kHz, thus there are going to be strong FM sidebands
around 36-40, 76-80 and possible 118-120 kHz around the carrier on
both sides.

Since there is some symmetry between the upper and lower sidebands, so
this may help reconstruct the missing sidebands if the other side of
the carrier is clean, while the other side is contaminated.

However, I have no idea if this has been attempted in practice.

I had a Yaesu FRG-7 receiver that used this lovely Wadley loop. If you subscribe to the theory that every beep and bloop you hear as you tune across the dial is a station, that is the receiver for you!

However, if you understand spurs and birdies, a different picture emerges. Lots of noise, too!

For 'normal' SMD work I use one of these big magnifying glasses with a fluorescent tube around it, a fairly standard article. If you can not find then, you may also look in a shop for needlework. For finer work and inspection, I use a 20x stereo microscope, bought for about $30 on Ebay. As I am 50, my eyes are slowly getting worse. Soldering with a temperature controlled Weller and 0.5 mm tin.

Succes, Wim

Thanks, guys. I think you covered what I wanted to know...

Now I have another question on the same subject. Imagine if you will,
a NBFM recieiver, set to listen on one particular channel. Now
consider 3 seperate sweep transmitters located say 100yds away. Each
sweeps slowly across the band which encompasses the RX's receive
channel.
Sweep transmitter 1 puts out only an unmodulated carrier wave. STX 2
puts out an FM signal of the same power level; STX 3 puts out an AM
signal of the same power. Assume the extent of modulation is likewise
identical - or as identical as it can be given different classes. Now,
which of the three TXs is going to 'take over' the RX channel for the
longest time? IOW, which of the TX signals appears broadest to the FM
RX?

Thanks,

p.

Source record: 28459

I am confused. The circuit on the link you provided shows an antenna. You need to get some sort of low pass characteristic between your transmitter and the antenna. That is what I was trying to suggest. Perhaps a capacitive tap feed to the ant instead of the inductive tap. Again, with only the osc, this is not easy:

```
Original ckt
+V
|
|------------0
|-----| Ant
|/ C
= O----------0
/|C6 I
| L L1
|-----|
|
|/ Collector
B-| TR1
|\ Emitter
****************************************

+V
| New circuit
|
|--------|-------------------0
C = Ca ant
O L1 |--------COIL--|----0
I |/ L2 |
L = C6 =Cb <- Low pass pi net
| /| |
|--------| gnd
|
|/ Collector
B-| TR1
|\ Emitter
```

I estimate Ca & Cb to be approx 100-150 pf. L2 resonates with (1/2)*(Ca series Cb)

If you are not using an antenna and just radiating from the circuit, then your only hope is to either box it up or reduce the TR1 current to reduce the harmonis content (increase R1... 200, 500, 1000, 2000,...)

There are a lot of variables here, but ...
"the same power. ...modulation is likewise identical" is rather un-defined since you have an AM & an FM sweeper.

If the bandwidth for the two modulated "sweepers" is about the same (i.e. AM & NBFM), I think they will produce near the same level of interference. The AM might be a little less since the side bands are only 25% the carrier power and the FM sidebands can be a higher percentage (I'm not too sure with NBFM, since NBFM side bands aren't much different from AM sidebands), but this depends upon the modulation amount at any given time. As the side bands get into the channel they start to cause trouble.
The carrier only sweeper will be a little better since it has no sidebands to get into the IF before the carrier does, so it'll have to get closer to center channel before causing trouble.

How-zat?

Paul,
You still need to be more specific:
What is the modulating frequency and deviation of the FM signal? Is it the modulation frequency a single tone or noise-like?. What is the IF bandwidth of the FM receiver? What is the sweep rate of the interfering signal? We'll assume the AM signal is modulated with the same frequency at 100% modulation.

In general, the CW signal would be least intrusive for a given sweep rate because it's energy is only in the IF of the receiver for a period of time equal to RXbw/sweeprate. If this time is small compared to the inverse of the post detection (audio) bandwidth, it might be inaudible. If the modulation is noise-like and the FM modulation index is high, the interference will be worse and longer in duration. If the FM modulation frequency is high, the modulation index is low, and the sweep rate is low, it could sound like 3 seperate signals sweeping through the passband (AM would be similar to this last case).

Whichever signal is strongest is going to "take over."

You CAN determine this yourself, given some frequencies, RF output levels, approximate gain/loss of the antennas, and the selectivity (bandwidth) of the receiver and the modulation indexes of the transmitters. Piece of cake.

Might I suggest you walk slowly away from the interfering RF fields to avoid ionization the neurons? Any more?

FWIW, Henry, I prefer to use an AC output 'wall wart' and install in
the unit to be powered a pair of diodes to supply + and - which I
filter and regulate down to what is needed. For that miniscule power
demand the filter caps and TO-92 regulators will take up little room.

I have a need to produce an accurate 4Mhz 50% dutycycle TTL squarewave to use as a timebase.

I have a 10Mhz IQD frequency standard of suitable accuracy. How can I divide this to produce the 50% duty cycle 4Mhz signal?. Is it even possible with logic alone?. I can see how to mix with either 6Mhz or 14Mhz, but this then detracts from the required accuracy.

Hi, I'm building a small valve communication receiver in an
effort to recapture some of the fun of my youth :)))
And I am trying to find a circuit of a simple valve CW Audio filter
Years ago I built one from a circuit that was in the ARRL handbook
about 60's vintage, that was superb, anyone got an old Handbook
of that vintage that could have a look and possibly scan the
info, or possibly have a good one of their own using standard
valve componants!! long shot I know :))
Thanks from Ron G3YUH ronayling@hotmail.com

Gee. I could have sworn Jim was hinting at the math approach.
Wouldn'tcha just love to predict that roll-off on paper and *then*
see it in real life? Starts with an "F", looks like a number,
sounds like a frog.

Do you recall if it was a twin-T filter? I might be able to find a tube
implementation. As I recall it took a twin
triode and used feedback.

Was your filter tunable?

Several approaches spring to mind. You stated "accurate" - they all provide
that, but jitter is introduced in all of them:

1. VCO at 4MHz, divide by 4 and lock to Fref = 1MHz from your 10 Meg source
divided by ten.

2. VCO at a multiple of 10M - say 40 MHz - locked to your 10M ref and
divided down (by in this case 10) to give 4 MHz output.

Both of the above may provide acceptable jitter.

3. a no-VCO approach - frequency double twice using XOR gates, then divide by
five and finally by two in say a 7490. Simple glue logic chips.

4. use a micro.

I would certainly expect both 3 & 4 to present more jitter than well-implemented
VCO solutions. If jitter is critical to the application, this needs to be
indicated.

Take a look at Analog Devices' line of DDS chips. Pretty much a one-chip (needs ucontroller to drive it) digital solution to turn your 10MHz clock into virtually any frequency below 5 MHz (in theory; below 4MHz in easy practicality). The AD9834 only consumes 20mw at 3.3 VDC. There are many other devices in the product line. Many have built-in comparators to produce square-wave output.

1386. FT707 ALC problem...help!

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-18 13:06:44 UTC
From: ablight@alphalink.com.au
Message-ID: <1fc7b362.0402180506.2409a431@posting.google.com>
Source record: 28473
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment

Hopefully someone has seen this before, or can offer a starting point to trace it down. (or a plausible theory - I'm getting that pissed off)

Problem - on some bands but not all, on TX SSB the front panel ALC meter doesnt work - the TX still has output, but very distorted and splattery EXCEPT if you go to the very top of the band via the VFO when it miraculously works. Looking at the ALC control line on the cro, when working a variable (speech rate) almost DC voltage is applied to the relevant ALC inputs to the RF and AF and IF boards. In the fault condition there is a modulation patttern on the ALC signal, in step with speech peaks.

What gives - my theory falls over on this one, I suspect the LPF on the output of the PA amp has gone faulty (as evidenced by VFO settings) but to pull it to pieces to check is going to be a real pain - this thing was designed by evil minded dwarfs who were determined to make life difficult in servicing - try and do ANYTHING with the front panel parts, or the rear PA module, and wires come loose and generate more faults - this it has done a few times now, so its getting very frustrating and time consuming!

As I said, on some bands it works, but on 80 and 15 (from memory, its 5 past midnight here at the end of a long day...) and the "where it is in the band" symptoms dont help either.

Any helpful suggestions, feel free to chuckle and be glad its not sitting on YOUR bench....

I would suggest using a 4MHz crystal oscillator as your VCO. Small varicap
to alter the VXO frequency (or use an ordinary diode or LED as the varicap,
see http://www.hanssummers.com/radio/varicap/varicap.htm). The inherent
stability of the VXO will allow you to use a very slow PLL, which will
result in minimal jitter.

Hi,

That was perhaps the "Selectoject" which used a pair of
12AX7 (ECC83) valves in a phase-shifting audio peak or
notch filter. It was designed to go between the detector
and the first audio amp but could, I suppose, be used
equally well externally. If you will let me have an
address, I'll copy it for you from the 1956 Handbook or
from the appropriate QST CD.

Source record: 28478

I have a few slow-motion drives with pointers that I'd like to equip with simple log scales. I have tried to split a half-circle scale by means of a compass, and found it to be quite doable, but 1) time-consuming, 2) messy, 2) leading to power-of-two end-of scale values (obviously) that are anything but intuitive. I am not an binary / octal / hex / kind of guy, and have no affinity for scales that end at 64 or 128 or G_d forbid 256. I also tried making a 0-100 scale by means of Excel / PowerPoint / Openoffice, but their rendering hits very soon an unsightly rough degree of approximation.

Is there any place on the web whence I can download some high-definition graph for a 0-100 or 0-180 scale? I'd print it out in large format and then reduce it to the size I need by means of an ANALOG photocopier.

TIA

Hi All;
Tonight I have a handy item>>
19" rack mount HomeBrew HV Power supply using 6336 rectifier tube,
5-20mfd@450volt FP Cans, Triad Xformer & Reactor.
Looks like it was almost finish but never completed. Complete with connectors
on back, see pics.
The chassis might have been used before this as there are a few extree holes
but the rest is nice, looks like a New panel & knobs. Meter is a Westinghouse
CX, 600V full scale. I suspect it can be used for HB receivers & Xmitters. If
you SS the Supply(pull the tube), you got 6.3 & 5 vdc filiments for other
things.
Untested & I have no idea where he got the schematic, I have none!
Someone has gotta need this.
Price is $40 + 20 lbs UPS from 11758.

I would guess the PLL is going out of lock. Do a careful alignment.

When the PLL is on the verge, the signal gets distorted and unstable.

If there is no ALC, it's probably because there isn't enough power output to overcome its threshold.

Just a guess; I've never worked on one of those rigs.

Bob

Multiply by four, then divide by five and by two. Or divide by five, then multiply by four and divide by two. For the best symmetry, you should expect to use a divide-by-two in the last stage, though you can get close to 50% with triggering off both rising and falling edges. There are other possible trick ways but the mpy/div are straightforward. You could, for example, divide the ref by five and a 4MHz VCO by two and build a PLL to control the 4MHz VCO.

Cheers,
Tom

>ANALOG photocopier.

Here's some alternates -

Office Depot and Office Max chains have "graph paper" with
many kinds of scales...1, 2, 3, and 5 decade log scales by
linear or log on the opposing axis.

Analog-copy an old slide rule's C or D scales...themselves
fairly accurate single-log. [not many slide rules in common use
nowadays, heh heh, would be a fitting sayonara for them]

To actually draw one's own scale, get access to an old T-Square
(ancient drafting implement) and lay out a right triangle. Let a
large log scale be the hypotenuse (that side of the triangle on a
slant). Use the T-Square to get parallel vertical lines intersecting
marks on the log-scale hypotenuse to the horizontal (or vertical)
axis. The size reduction from original log scale to the new one
depends on the angle of the hypotenuse...very easy to "calibrate"
to start the marking.

Digital copying will depend on the quantization error of the number of
available pixels in the image. Most pronounced in absolute black-
and-white mode. Greyscale and color will show up in gradations and
one has to guess at the exact point of the log markings.

For very fancy dials, most industrial-strength photo shops can handle
up to 4x original art (perhaps to 11" x 14"), shoot it, reduce it to
very-close-to-desired dimension, and even opaque any clear spots on
the negative. That method can be the basis for a chemical etching of a
metal dial. Cost varies so it is best to inquire first on that method.

>14Mhz, but this then detracts from the required accuracy.

A more direct way, with very little jitter, is to double the 10 MHz
reference with a dual diode arrangment, output tuned to 20 MHz,
then into amplification (if needed), through a Schmitt inverter,
another (!) dual diode doubler with output tuned to 40 MHz. Again
amplification (if needed) and another Schmitt inverter to square
up the 40 MHz. Divide the 40 MHz by 10 in a Johnson counter to
achieve the 50% duty cycle. Broad tuning, no real problems there.
Very direct. Minimal jitter.

Johnson counters aren't common but they aren't made from
unobtainium either. The CD4017 is an example and still available
although it isn't fast enough for this application. Dividing by 10 via
a Johnson counter needs a 5-stage shift register arrangement
which can be done from 74LS or 74F or 74AC components (a
4-bit SR IC plus a flip-flop to complete the 5 stages).

If operating at slower rates, the 50% duty cycle would appear at
the "Carry Out" pin of a CD4017.

A good simple explanation of Johnson counters is at:

http://www.play-hookey.com/digital/johnson_counter.html

Some other suggestions might suggest themselves if you explain
the "timebase" in more detail.

Depends on what you call "practical".

I know that one type of atomic clock uses a one stage frequency multiplier
to go from about 10MHz to about 9.1GHz.

A slow edged square wave follows the 1/N rule to about the point where the
rise or fall time is equal to half a cycle of the harmonic frequency.
From that point up, the spectrum falls off at a rate of at least 1/n^2.
Usually it is faster than that.

If we assume that the 5nS rise time is the input to a stage, we can use a
fast transistor to effectively speed the edge up.

Agreed, a VCXO is a good way to go if you do need a VCO.

Remember, the o/p didn't reference any jitter sensitivity in the task, which may
be simple timing or gated counting of a pulse train. Neither is
jitter-sensitive.

If jitter isn't an issue, I'd personally KISS and go with #3. Small footprint,
small dissipation, no tuned circuits, no PLL parameters to calculate, no VCO's
to build, no VCXO's or xtals to buy. Only one RC time constant to calculate (or
optimise by SOT) to minimise jitter if inclined to bother.

Hi Bob,
a good theory and got me going - but then I realised it is an analog
superhet, ie no horrible nasty almost digital things. But a valid
point - will look at the o/p of the mixer on the affected bands - the
vfo runs a constant 5-5.5Mhz, so possibly the heterodyne osc. is
playing up - although, a rough check has shown the drive levels to the
PA board are constant irrespective of fault condition.

Hi,
Every one knows, that e.g. a simple RC-parallel circuit has a frequency-dependent impedance-characteristic (Absolute Value) - the impedance (Abs) raises as the Frequency approaches zero. As a formula: Zin = 1/(1/R + i w C) , where i ist the imaginary number and w the frequency.

Now the hard part. How does one create an Impedance, which decreases "slower", for frequencies close to zero but then decreases "faster" for higher frequencies, than the simple parallel RC-Circuit?
Is there some kind of procedure like the one for syntesizeing LC-Filters (Butterworth, Chebychev,..)?

Simply increasing C does not really help, because this equals a factoring of the frequency.
Increasing R does not help as well, as it seems.

I hope one of you cracks can help me out.
So far, thanks for reading.
Diego Stutzer

>Diego Stutzer

I've never looked into changing the slope of impedances,
but depending on what you are doing you might be
interested in how to control the slope of filter
transfer functions to get something other than 6*N
dB/octave. A common requirement is to get 3 dB/octave,
which is done by cascading normal low-pass and high-pass
stages in a piecewise-linear approximation. The slope
starts down at -6 dB/oct then it hits a +6 stage which
flattens it out, then another -6 stage, etc. You can get
closer to the desired slope by having more stages with
closer spacing. If you are going to build a one-off version,
you might want to use buffered stages so they don't
interact and you can design your network from the Bode
plots. If you are in mass production, you may want to
skip the buffers and spend a lot more time dealing
with the interactions. Without buffers, you probably won't
be able to get a very wide frequency range, but I have
seen this approach used for generating pink noise
from white noise over a useful portion of the audio
range.

Hope this helps!

Do you need the accuracy of the frequency standard? Why not just buy a
little 4MHz CMOS crystal oscillator?

If jitter and accuracy were important I'd either (hobby use) build a VXCO
with an 8MHz crystal referenced to 2MHz from the standard or (for a customer
design) buy an integrated 4MHz VXCO and reference it to 2MHz from the
standard. In either case I'd use the phase comparator from a 74HC4046 or an
exclusive OR gate. You'll be using a divide-by 5 which can be had from a
74HC390 if they're still available, and a divide-by 2 or 4, which can be had
from just about anything -- including the same 74HC390 if your hookup is a
little perverse. All the logic _could_ be done on a PAL, of course.

Come to think of it if absolute accuracy is important but jitter isn't you
can just use the oscillator from the '4046 as well, with the same division
scheme.

The best antenna is not the longest thing you can put up, unless one of the many minor lobes you create will point exactly where you want to go at a radiation angle you need, and this is highly unlikely, but it does sometimes happen.

The best thing to do is decide where you'd like to reach, for example, which continent. Are you a DXer or do you do mostly local rag chews? What frequency bands would you like to operate, and what size constraints do you have to live with? Are there any natural supports you'd like to take advantage of? Do you need multiband operation? Do you have an deed restrictions on what you can put up?

Study the radiation patterns of dipoles, verticals and if you have the space, long wires.

Do you have a tuner?

Remember, no antenna creates RF to get "gain", they only focus it. The ideal RF antenna would radiate equally well in all directions. Since you live on earth, the effect of height is an issue, as is the ground effect on the pattern.

The best antenna to start with for a newbie is a windom cut for the lowest band that will fit on your lot. With this kind of antenna you can run all harmonic bands (ie 80M will cover 40M,20M,10M while 40M will cover 40M, 20M, 10M) quite well and not require a tuner. Several of the WARC bands will work ok too but the SWR may be a little higher. I regularly use my 80M windom on all bands here, most of them without a tuner, and the rigs tuner is good enough on the one or two where the SWR is just over 2:1 which isn't an issue, it just causes the radio to reduce power.

The second best antenna is a vertical, but most newbies screw up the installation. You either need 4 elevated radials or you need lots of radials on the ground. Lots means 16 or more. Again, the literature is full of information on these topics, and there was even an article a few months ago in QST I think where someone did a study on the best use of the wire for a vertical ground plan - ie more or longer radials for a given length of wire to optimize results.

The vertical is a good newbie antenna because it radiates equally well (some say equally poorly) in all directions. Although some of that will go to places where no one lives, if you have a good ground plane the low angle of radiation will be to your advantage. One caution, if you live with a lot of neighbors around verticals pick up noise more than horizontal antennas and this can be a big issue. In that case stick with a windom.

If you have the money and the time and a computer, try purchasing an antenna modeling software packet. I use NEC4WIN but there are many. With this, you can model various wire configurations quickly and see EXACTLY what they will do in terms of gain/loss/pattern etc. This will save you a lot of time and money building things that don't work.

Finally, if your interest is local ragchewing, a low horizontal antenna may be just fine.

I have an extensive antenna farm here, quads, yagis, dipoles, verticals, etc. and over the past 35 years I've tried everything. The best overall antenna, the one that I keep coming back to as a standard or default for comparison is the windom. This off center fed device is fed at a point where the SWR is tolerable on harmonically related bands using a matching balun. My favorite was made by Fritzel, but I don't think they make them anymore, but an internet search will turn up several suppliers and/or plans for your own. The biggest issue in a windom is just the balun, and I recommend CWS Bytemark products if you can get them.
